A WEEKLY

ILLUSTRATED JOURNAL OF SCIENCE

VOLUME CXV

JANUARY, 1925, to JUNE, 1925

"*To the solid ground*
Of Nature trusts the mind which builds for aye."—WORDSWORTH.

London
MACMILLAN AND CO., LIMITED
NEW YORK: MACMILLAN COMPANY

[*Nature*,
August 15, 1925

INDEX.

NAME INDEX.

Abbot (Dr C G), Biographical Byways Dr S P Langley, 455, to lead an expedition for the choice of a site for the making of observations of the Solar Constant of Radiation, 772, and colleagues, Provisional Solar-Constant Values, 957
Abbott (G), [death], 130, [obituary article], 201
Abolin (L), The Changing Colour of the Munnow, 62
Abraham (H), and R Planiol, Magnetic Sesquioxide of Iron, 930
Ackeret (J), Das Rotorschiff und seine physikalischen Grundlagen, 462
Adair (G S), The Direct Method of measuring the Osmotic Pressure of Proteins, 857, The Osmotic Pressure of Hæmoglobin and the Absence of Salts, 857
Adam (N K), The Molecular Mechanism of Capillary Phenomena, 512, and G Jessop, An Explanation of the so-called "Intertraction Phenomenon" between Solutions and the Molecular Significance of Negative Surface Tension, 553
Adams (Dorothy), The Crystalline Lens, 553
Adams (L H), The Cooling of the Earth, 98
Aitchison and Johnson, Fatigue Strength of Steels, 994
Alcock (Mrs N L), Bark Scorch of Willows, 135
Alexander (J), Colloid Chemistry an Introduction, with some Practical Applications, Second edition, 634, Protective Colloids, 172
Alkins (W E), *Clausilia bidentata* (Ström) and *Cl cravenensis* (Taylor), 285
Allan (R S), The Geology of the Chatham Islands, 959
Allbutt (Sir T Clifford), and others, Essays on the History of Medicine Presented to Karl Sudhoff on the occasion of his Seventieth Birthday, Nov 26, 1923 Edited by Dr C Singer and Dr H E Sigerist, 372, [obituary article], 387, [death], 300
Allen (F), and A Hollenberg, The Tactile Sensory Reflex, 854
Allen (Prof H S), Chemistry and the Quantum Theory, 452, awarded the Makdougall-Brisbane prize of the Royal Society of Edinburgh for 1920–24, 775
Allen's Commercial Organic Analysis, Edited by S S Sadtler, Dr E C Lathrop, and C A Mitchell Vol 2, Fifth edition, 114
Allison (Dr S K), On the reported $K\beta_4$ Line in the X-ray Spectra of Molybdenum and Palladium, 978, and W. Duane, On Scattered Radiation due to X-rays from Molybdenum and Tungsten Targets, 590
Allison (Dr. V D), appointed J C White lecturer in bacteriology in the Queen's University, Belfast, 33
Allmand (Prof. A. J.), and V S Puri, The Effect of Superposed Alternating Current on the Anodic Solution of Gold in Hydrochloric Acid, 480, The Effect of Superposed Alternating Current on the Polarisable Primary Cell Zinc—Sulphuric Acid—Carbon Part I., 177
Alty (Dr. T.), appointed professor of physics in Saskatchewan University, 997
Amos, The Practice of Ensilage, 474
Amundsen (Capt.), Flight to the North Pole, 848, 918; return of, 988
Anderson (Miss I.), The Genetics of Variegation and Leaf-structure in Ferns, 929
Andrew (G), The Llandovery and Associated Rocks of Garth (Breconshire) The Relations between the Llandovery Rocks of Llandovery and those of Garth, 624
Andrews (J. P), The Variation of Young's Modulus at High Temperatures, 589
Andrieau, The Andrieau Motor, 358
Angus (H T), and P F Summers, The Effect of Grain-size upon Hardness and Annealing Temperature, 661
Annandale (the late Dr N), Primitive Mural Decoration in Southern India, 206
Anrep (Dr G V), A New Method of Crossed Circulation, 357, and I de B Daly, The Output of Adrenaline in Cerebral Anæmia, as studied by means of Crossed Circulation, 357, and Prof E H Starling, Central and Reflex Regulation of the Circulation, 357
Antram (C B), Butterflies of India, 115
von Antropoff (Prof A), offered the chair of physical chemistry at the Chemical Institute of Bonn University, 140
Appleton (Dr A B), A Hopkinson, and V C Pennell reappointed demonstrators of anatomy in Cambridge University, 964
Appleton (Prof E V), The Propagation of Radio Waves over the Earth, 382, and M A F Barnett, Local Reflection of Wireless Waves from the Upper Atmosphere, 333, Wireless Signal Strength Measurements made during the Solar Eclipse of January 24, 1925, 625
Appleyard (R), Depth-recording with Plankton-nets, 870
Archbutt (S L), A Method of Improving the Properties of Aluminium Alloy Castings, 661
Armellini-Conti (G), and G Armellini, The Variation of the Luminous Intensity of the Moon during the Total Eclipse of August 14, 1924, 143
Armstrong (A L), The Exploration of Caves in Derbyshire, 24, Recent Excavations on Palæolithic Sites at Cresswell Crags, Derbyshire, 658
Armstrong (Dr E F), appointed managing director of the British Dyestuffs Corporation, 775, appointed a member of the Dyestuffs Industry Development Committee, 956, and Dr T P Hilditch, A Study of Catalytic Actions at Solid Surfaces Pts XII and XIII, 517
Armstrong (Prof. H E), A Course of Faraday, 568, Huxley's Message in Education, 743, Dr H T. Brown, 307, Teaching in English Schools, 140, The Faraday Benzene Centenary, 870, 1010, The Life of Lord Rayleigh, 47, The word "Scientist" or its Substitute, 85
Arnulf (A.), The Ionisation of Potassium Vapour under the Influence of Visible Light, 894
d'Arsonval, A New Direct-current Generator giving 500,000 volts, 999
Artom (C), Numerical Disproportion of the Sexes in *Gambusia holbrooki* (Grd) analysed as to its Manifold Causes, 402
Askwith (Lord), address at annual meeting of the British Science Guild, 658
Aston (Dr F W.), elected a member of the Athenæum Club, 581; Isotopes, Second edition, 222
Atkins (Dr. W. R. G), The Preservation of Fishing-nets, Mosquito-nets, and Tent Fabrics, 701, and G. T. Harris, Seasonal Changes in the Water of Ponds, 315

Atkinson (E J), A Vector-trolley Apparatus, 280
Atkinson (L B), The Scientific Principles of Artificial Incubation, 282
Aubel (E), and J. Salabartan, The Mechanism of the Production of Hydrogen at the Expense of Glucose by the Coli Bacillus, 823
Austin (L W), Radio-field Intensities, 816
Avel (M.), The Vacuome and Apparatus of Golgi in the Vertebrates, 663
Axene, Ltd, A New T-square and Drawing-board, 439
Ayyar (A S R), A Note on Arddhanārīśvara, 107
d'Azambuja (L), Moving Absorbing Vapours at Great Heights above the Photosphere, 473, Observation of remarkable Protuberances, made at the Meudon Observatory, January 24, 1925, before the Eclipse of the Sun, 358

B. (F F P), Ether and the Metaphysical Mind, 533
Bachofen-Echt (A), The Discovery of Iguanodon Tracks in the Neocomian of the Island of Brioni, near Pola, 627
Back (Dr E), und Prof A Landé, Zeemaneffekt und Multiplettstrukter der Spektrallinien, 559
Bailey (E B), Perthshire Tectonics Loch Tummel, Blair Atholl, and Glen Shee, 929; The Tertiary Igneous Geology of the Island of Mull, 966
Bailey (G L), and R Genders, The Density and Constitution of the Industrial Brasses, 662
Bailey (Dr K C), New Synthesis of Urea, 317; The Identity of "Alumen" in Pliny's Natural History, 764
Baillaud (J), Stellar Spectrophotometry, 134
Baird (J L), demonstration of Wireless Television, 505
Bairstow (Prof L), The Rotor Ship and Aeronautics, 462; Fluid Velocity and Pressure, 152
Baker (C), catalogue of second-hand scientific apparatus, 991
Baker (E A), The Law of Blackening of the Photographic Plate at Low Densities, 214
Baker (E C S), Field Naturalists and Evolution, 995
Baker (H F), A Transformation of Segre's Figure in Space of Four Dimensions; the Equation of Kummer's Surface, 357
Baker (T. Thorne), Estimating the Qualities of a Photographic Plate, 264
Baldet (A.), An Alignment of Radioactive Springs in the Region of Velay (Haute-Loire), 694, The Distribution of Radioactive Springs, 923
Baldet (F.), Observations of the Planet Mars, 34; The Influence of Pressure on the Band Spectra of Carbon in the Thermo-electronic Bulb, 859; The Third Negative Group of Carbon, the so-called Comet-tail Spectrum, 626
Balfour (Dr. A), Historical Aspects of Malaria, 17, Reflections on Malaria, 625
Balfour (H), Fish Traps in Eastern Asia, 509; Navigation and Fishing on the Ganges, 622; Stencil in Fiji, 814; The Origin of the Art of Stencilling in the Fiji Islands, 34; The Status of the Tasmanians among Stone Age Peoples, 858
Balfour (Lord), A Committee of Imperial Research, 845
Ball (W W Rouse), [death], 542; [obituary article], 808
Ballantyne (Miss Frances M.), The Continuity of the Vertebral Nervous System Studies on *Lepidosiren paradoxa*, 929
Balls (Dr W. L.), The Sound of Lightning, 912
Baly (Prof. E C C), Spectroscopy 2 vols. Third edition, 153, and Dr Elizabeth Semmens, The Selective Photochemical Action of Polarised Light. I. The Hydrolysis of Starch, 821
Banachiewicz (Prof), Orkisz's Comet, 921
Banerji (Dr S K), Depth of Seismic Foci, 618, Vernier Wireless Time-signals, 912
Bangham (D H), and J. Stafford, The Velocity of Oxidation of the Metals and the Structure of Coloured Oxide Films, 83
Banister (H.), appointed demonstrator in experimental psychology in Cambridge University, 927
Bär (Dr. R.), The Abnormally Low Voltage Electric Arc, 549
Barclay-Smith (Prof. E), appointed a fellow of King's College, London, 355
Barcroft (Prof. J), The Pigmentation of Animals, 679; and others, The Function of the Spleen, 397
Barkas (W. W.), On the Distribution of Particles in Colloidal Suspensions, 481
Barker (Prof. A. F.), Genetics and Wool Production, 687; Touch and Sight *v* The Microscope in Wool Classing and Sorting, 226, University Ideals, 785
Barker (J), reappointed Frank Smart student in botany in Cambridge University, 784
Barker (Dr T. V), Crystal Formation, 208
Barkla (Prof C G.), and Gladys I Mackenzie, The Coherence of Superposed X-Radiations, 942
Barlow (E W.), Upper Air Circulation of the Atlantic, 655
Barnard (K. H.), A Revision of the Family Anthuridæ (Crustacea, Isopoda), with Remarks on certain Morphological Peculiarities, 554; Report of the South African Museum, 885
Baron (B), gift to the Hebrew University, Jerusalem, 907
Barr (Prof A), The Optical Instrument Maker and Scientific Investigation, 311
Barrabé (L), and P Viennot, The Discovery of an Oil-bearing Layer at Gabian (Hérault), 35
Barré and Schnell, The Propagation of Sound Waves in the Soil, 931
Barrett (Sir W F), [obituary article], 880
Barringer (D M), The Meteor Crater of Arizona, 244
Barthoux (J), Description of a New Mineral, Dussertite, 359
Bartrum (C O), Double Rainbows, 16
Barus (Dr. C), The Diffusion of Hydrogen into Air, measured by the Interferometer U-gauge, 179
le Bas (G Z L), Experimental Studies on *Dibothriocephalus latus* in Man, 510
Bateson (Dr W), Huxley and Evolution, 715, Mendeliana, 827
Bather (Dr. F A.), The word "Australopithecus" and others, 947
Bauer (Dr L A), elected a corresponding member of the Russian Academy of Sciences, 312, Further Evidence regarding the Correlation between Solar Activity and Atmospheric Electricity, 537, The Sun and Atmospheric Electricity, 279
Baxter (E F.), appointed lecturer in applied mathematics in Durham University, 997
Baxter (G. P), and H W. Starkweather, The Density of Oxygen, 483
Bayle (E.), and R Fabre, The Urinary Elimination of Alkaloids derived from Isoquinoline and especially Hydrastine, 555
Bayly (Dr. H W.), Venereal Disease: its Prevention, Symptoms, and Treatment. Second edition, 11
Beach (Prof S A), [death], 93
Bear (Prof. F. E.), Soil Management, 152
Beasley (C. G.), "Local Geography," 652
Bock (C), Microscopic Images, 691
Bedale (Miss E. M), The Effects of Posture and Rest in Muscular Work, 319
de Beer (G. R.), A Problematical Organ in the Lamprey, 27; and Huxley, Vitality of Jelly-fish, 62
Beit (Sir Otto), elected a member of the Athenæum Club, 241
de Belaevsky (V.), The Rupture of the Bouzey Dam, 482
Belaiew (Col. N. T.), On the Inner Crystalline Structure of Ferrite and Cementite in Pearlite, 786
Benedicks (Prof. C.), On the Hardness of Manganese Steel, 230; Space and Time: an Experimental Physicist's Conception of these Ideas and of their Alteration, 408
Benedict (G.), The Neutral Bath and its Relation to Body Heat, Body Posture and Minor Muscular Movements as affecting Real Production, 483
Bennet (Rev. A.), F. W. Shurlock, 277
Berget (A.), A Marine Refractometer with Double Deviation, 590
Bergoiné (Prof. J), [obituary], 93
Berkeley (L. M.), North Star Navigation, 637
Berkey (C. P.), and F. K Morris, Geology of the Gobi, 28
Berry (A.), elected vice-provost of King's College, Cambridge, 283

Berry (Dr. E. W.), The Middle and Upper Eocene Floras of South-eastern North America, 819
Bert (L.), A General Synthetical Method for the Preparation of *w*-Chlorallyl Cyclic Derivatives and through these Acetylenic Hydrocarbons, Alcohols, and Aldehydes, 967
Berthelot (A.), and G. Ramon, The Agents of Transformation of the Toxins into Anatoxins, 359
Berthelot (C.), Flotation Method of Cleaning Coal, 511
Bertrand (G.), and M. Machebœuf, The Presence of Nickel and Cobalt in Animals, 930; and M. Mokragnatz, The General Presence of Nickel and Cobalt in Arable Earth, 250
Bertrand (Prof. G. É.), elected an honorary member of the Royal Institution, 1016
Besson (Mlle.), [death], 845
Bezssonoff (N.), Some Data on the Nature of the Anti-scorbutic Principle known as Vitamin C, 663
Bezzi (Prof. M.), The Bombyliidæ of the Ethiopian Region based on Material in the British Museum (Natural History), 152
Bhatia (B. L.), and S. Setna, Some New Gregarines, 437
Bialosuknia (W.), and B. Kaczkowski, Differentiation of Breeds by Serological Methods, 547
Bianchi (Prof. L.), elected an associate of the Académie royale de Belgique, 25
Bidder (Dr. G. P.), Constant Differential Growth-ratios and their Significance, 155; Growth and Death, 480, Prof. A. Dendy, 541; The Origin of Sponge-spicules, 298, The Mortality of Plaice, 495
Bieler (Dr. E. S.), Band Spectra of Lead Isotopes, 980
Bigiavi (D.), Action of Nitrous Acid on the Azophenols, 402
Bigourdan (G.), The Equations, of Various Origins, which may affect the Pendulum Corrections employed at the Bureau International de l'Heure (B.I.H.) during the Five Years 1920–1925, 929; The Perturbations of the Hertzian Waves during Transmission to Great Distances, 446, The Propagation of Hertzian Waves to Great Distances, 358
Birchby (W. N.), White Light Interference Fringes with a Thick Glass Plate in One Path, 179
Birkenhead (Lord), the work of Prof. A. H. Sayce, 809
Birmingham (Bishop of), conferment upon the, of a degree by Aberdeen University, 551
Birtwell (Constance), D. A. Clibbens, and B. P. Ridge, Oxy-cellulose, 317
Bisat (W. S.), Carboniferous Goniatites, 851
Bischoff (H.), Hymenoptera I., II., 565
Biswas (K.), Sub-aerial Algæ of Berkuda Island, 931
Bjerknes (Prof. V.), Hydrodynamics and Electrical Analogies, 246
Black (D. H.), High Energy γ-Ray from Thorium Disintegration Products, 226
Blackburn (C. M.), An Application of the Quantum Theory of Band Spectra to the First Negative Deslandres Group of Carbon, 590
Blackett (P. M. S.), appointed assistant demonstrator of experimental physics in Cambridge University, 784, The Ejection of Protons from Nitrogen Nuclei, photographed by the Wilson Method, 212
Blackman (Miss Winifred), An Egyptian Survival, 851
Blaise (E. E.), and Mlle. M. Montagne, The Preparation of the Acyclic δ-diketones, 930
Blanc (L.), and G. Chaudron, The Magnetic Study of the Stable Form of the Sesquioxides of Iron and Chromium, 359
Blanchet (G. H.), Survey Work in Northern Canada, 316
Bloch (Prof. E.), translated by P. A. Smith, The Kinetic Theory of Gases, 189
Bloch (L.), E. Bloch, and G. Déjardin, The Spark Spectrum of Neon, 626
Bloch (L. and E.), The Spark Spectrum of Iron in the Schumann Region, 141; The Spark Spectrum of Tungsten in the Schumann Region, 286
Blondel (A.), Acoustic Selection and Radiogoniometry, 694; A New Method for the Harmonic Analysis of the Curves of Electromotive Force of Alternators, 446
Blum (L.), M. Delaville, and van Caulaert, Modifications of the Blood resulting from Anaphylactic Shock, 71; M. Delaville, and van Caulaert, The Pathogeny of Rickets, 250
Boas (F.), and F. Merkenschlager, The Biology of White Mustard, 886
Boccardi (J.), Averaging by Tenths of a Year in Variations of Latitude, 70
Bohr (Prof. N.), awarded the Barnard medal of Columbia University, 885; elected a foreign member of the U.S. National Academy of Sciences, 849; The Theory of Spectra and Atomic Constitution. Three Essays. Second edition, 559
Bolton (Dr. H.), Insects from the Coal Measures of Commentry, 977
Bolton (J.), [obituary], 345
Bolton (Prof. J. S.), Mind and Brain, 848
Bonar (Dr. J.), Malthus and his Work. Second edition, 406
Bone (Prof. W. A.), D. M. Newitt and D. T. A. Townend, Gaseous Combustion at High Pressures, Pt. V., 998
Bonnevie (Mlle. Kristine), Heredity in Finger Prints, 27
Boomer (Dr. E. H.), Chemical Combination of Helium, 16
Borchers (Prof. W.), [obituary], 272
Bordet (J. and Mlle. M.), The Bacteriolytic Power of Colostrum and Milk, 34
Bordier (H.), Experiments in Medullary Radiotherapy, 519
Borley (J. O.), and D. E. Thursby-Pelham, Report on the English Plaice Investigations in the North Sea during the Years 1921–1923, 969
Born (Prof. A.), Isostasie und Schweremessung ihre Bedeutung für geologische Vorgänge, 487; Physical Aspects of Chemical Combination, 172
Born (M.), and J. Franck, Atomic Combination and the Quantum Theory, 585
Born (Prof. Max), Translated by H. L. Brose, Einstein's Theory of Relativity, 408, Herausgegeben von Dr. F. Hund, Vorlesungen über Atommechanik Erster Band, 559
Boschma (H.), The Nature of the Association between Anthozoa and Zooxanthellæ, 591
Bose (Sir J. C.), The Physiology of Photosynthesis, 44, Transmission of Stimuli in Plants, 49, 457
Bostwick (A. E.), The word "Aeroplane," 650
Boutaric (A.), and G. Corbet, The Critical Temperature of Solution of Ternary Mixtures, 106
Bowen (I. S.), and Prof. R. A. Millikan, Series Spectra of Two-valence-electron Systems and of Three-valence-electron Systems, 422
Bower (Prof. F. O.), Teaching of Biological Science, 712
Bowman (Dr. A.), appointed lecturer on the scientific study of fisheries in Aberdeen University, 176
Bowman (Dr. I.), The New World Problems in Political Geography Revised and enlarged edition, 327
Boyer (J.), Catalogue de photographies documentaires, 472
Boys (Prof. C. V.), Personal Impressions [Huxley], 751, Spiral Springs of Quartz, 944
Boyson (V. F.), The Falkland Islands. with Notes on the Natural History, 940
Braak (Dr. C.), Climate of the Netherland Indies, 655
Bradfield (W. W.), [obituary], 503
Bradford (Sir John Rose), conferment upon, of the title of emeritus professor of medicine by London University, 355
Bragg (Sir William) elected president of the Institute of Physics, 884, Concerning the Nature of Things Six Lectures delivered at the Royal Institution, 523, The Investigation of the Properties of Thin Films by means of X-rays, 131, 266, The Need of Increasing Knowledge of Science, 658, The Romanes Lecture, 856, and Prof. W. L. Bragg, X-rays and Crystal Structure Fourth edition, 6
Bragg (Prof. W. L.), Model illustrating the Formation of Crystals; Diffraction Gratings constructed to illustrate the Effect of Crystals on X-rays, 482
Braid (Major K. W.), appointed professor of agricultural botany in the West of Scotland Agricultural College, 820
Brambell (Dr. F. W. R.), The Oogenesis of *Gallus Bankiva*, 893; The Part played by the Golgi Apparatus in Secretion and its Subsequent Reformation in the Cells of the Oviducal Glands of the Fowl, 286, The second edition of Dr. L. Doncaster's An Introduction to the Study of Cytology, 224

Brammall (A), The Association of Lime with other Oxides of RO-type in Minerals, 858
Brandegee (T. S), [death], 952
Brauner (Prof B), awarded the cross of a chevalier of the French Légion d'Honneur, 132 , the seventieth birthday of, 650
Brenchley (Dr Winifred), and H G. Thornton, The Relation between the Development, Structure, and Functioning of the Nodules on *Vicia Faba* as influenced by the Presence or Absence of Boron in the Nutrient Medium, 249
Brennen (H), Chemical Studies on the Isotopes of Lead, 359
Brentano (J), A Focussing method of Crystal Powder Analysis by X-rays, 589
Breuil (Abbé H), awarded the Daniel Giraud Elliot medal of the U S National Academy of Sciences, 616 , Palæolithic Man in Central Europe, 437
Bridel (M), The Presence of very Large Quantities of Free Maltose in the Fresh Tubercles of *Umbilicus pendulinus*, 35 , and C Charaux, Rhamnicoside, a New Glucoside, the Generator of Chinese Green, 695 , and C Charaux, The Products of the Ferment Hydrolysis of Rhamnicoside Primeverose and Rhamnicogenol, 859
Bridgman (Dr P W), Physical Properties of Single Metallic Crystals, 136
Bright (T B), Methods of Examination of Mildewed Cotton Material, 553
Brigl (Dr P), nominated professor and director of the Institute of Agricultural Chemistry, Hohenheim, 248
Briner (E), The Origin of Radioactivity, 1000
Brinkworth (J H), The Measurement of the Ratio of the Specific Heats using Small Volumes of Gas, 321
Briscoe (H V A), and P L Robinson, Atomic Weight of Boron, 816 , and P L Robinson, Atomic Weight of Bromine, 438
Bristowe (W S), Sound Production by Insects, 640
Britton (Prof N L), elected a foreign member of the Linnean Society of London, 849
Broca (Prof A), [death], 578
Broca (A), The Rational Mounting of Stringed Instruments, 519
Broglie (Duc de), Les rayons γ de haute énergie et leur effet photoélectrique, 461 ; A Suggested Explanation of the Quantum Theory, 549 ; and J Thibaut, Absorption of Radiation by the Emitting Atom, 439
Brooks (A H), [death], 93
Brooks (C. E P), The Climatic History of the Fiord Countries, 68
Broom (Dr R), Some Notes on the Taungs Skull, 569
Brough (P.), J McLuckie, and A. H K. Petrie, An Ecological Study of the Flora of Mt Wilson, Pt I , 179
Brown (B), A Luminous Spider, 981
Brown (C B), and R. A Baldry, On the Clay Pebble-bed of Ancon (Ecuador), 694
Brown (Prof E), Gravitational Forces in Spiral Nebulæ, 776
Brown (E W), Tidal Oscillations in the Lava Pit of Kilauea, 688
Brown (Dr H T), [death], 239 , [obituary article], 307
Brown (J M), Some Collembola from Mesopotamia, 625
Brown (K P), appointed lecturer in clinical surgery in Edinburgh University, 856
Browne (Major G St J Orde), The Vanishing Tribes of Kenya : a Description of the Manners and Customs of the Primitive and Interesting Tribes dwelling on the Vast Southern Slopes of Mount Kenya and their Fast Disappearing Native Methods of Life, 866
Browne (Rev H C), The Influence of the Fitzgerald Contraction upon Distance Measurements and Clock Times, 70
Browne (W. R), The Petrology of the Prospect Intrusion, 555
Brownlee (G), The Interpretation of certain Empirical Standards in their Application to Irish Butter, 402
Brownlie (D.), Some Notes on a Neglected Worthy, John Patison of Airdrie, 204
Brues (C. T.), The Fauna of Thermal Waters, 483
ten Bruggencate (Dr. P), The Absorption of Light in Open Star Clusters, 61
de Bruin (T. L.), and Prof. P. Zeeman, On a Connexion between the Spectra of Argon and Ionised Potassium, 116
Brumpt (Prof. É.), Prophlaxis against Malaria and Sleeping Sickness, 955
Brunhes (J.), translated by Prof I. C. Le Compte. Edited by I. Bowman and Prof. R E Dodge, Human Geography : an Attempt at a Positive Classification —Principles and Examples, 76
Bruni (G), and G R. Levi, Solid Solutions between Compounds of Elements of Different Valencies, 402
Brunt (Capt D), Instability of Viscous Fluid Motion, 300
Brus (G.), The Action of Chlorine on a-pinene, 967
Buchanan (Dr G), appointed lecturer in bacteriology in Edinburgh University, 856
von Buddenbrock (Prof W), Grundriss der vergleichenden Physiologie Erster Teil, 938
Budgen (Dr N F), Cadmium, 779 , Cadmium its Metallurgy, Properties and Uses, 793 , Pyrophoric Alloys, 172 , Typographic Inks, 352 , Zinc Oxide Industry, 511
Bugnon (P), Leaf Homologies in the Sweet Violet : Stamens and Carpels, 823
Buisson (H), and C Jausseran, The Spontaneous Reversal of the Lines in the Spectrum of Neon, 510
Bulman (O M B), Structure of a Dendroid Graptolite, 395
Bunting (D), The Influence of Lead and Tin on the Brittle Ranges of Brass, 662
Burne (R H), awarded the honorary medal of the Royal College of Surgeons of England, 97
Burnet (Prof), The Problem of Aristotle, 278
Burtt-Davy (Dr J), Poisonous Plants and Live-Stock, 438 , The Tropical Element in the Arborescent Flora of the Transvaal, 518
Butler (Dr. A G), [death], 882
Butler (J A V), Heterogeneous Equilibria, 354
Butler (W W), gift to Birmingham University, 398
Butterworth (S), The Alternating-current Resistance of Solenoidal Coils, 177
Buxton (L H Dudley), The Stoney Indians of the Bow River, Alberta, 518

Cadbury (W W), Anthropology of the Chinese, 437
Calderwood (W L), The Relation of Sea Growth to the Spawning Frequency in *Salmo salar*, 482
Caldwell (O W), Spirit of Modern Science Instruction, 660
Callister (R. C), Australian China Clays, 28
Callow (E H.), The Velocity of Ice Crystallisation through Supercooled Gelatin Gels, 858
Cambage (R. H), Acacia Seedlings Pt X , 555
Cambridge Instrument Co , Ltd , booklets on Direct Current and Alternating Instruments, 921 ; list of Thermoelectric Pyrometers, 349
Cameron (W H. B), The Possibility of reproducing the Electrical Conditions of the Nitrogen Afterglow, 122
Camichel (C), L. Escande, and M Ricaud, The Flow of Viscous Liquids round an Obstacle, 999
Campbell (A.), A Direct-reading Frequency Meter of Long Range, 178 ; The Determination of Resistance in Terms of Mutual Inductance, 177
Campbell (Dr. N R), The Need for a Universal Language, 381
Campbell (Dr. W W), The Halley Lecture, 997
Canney (E E.), Climatic Conditions for Cotton Growing, 438
Cannon (Dr H. G), Ectodermal Muscles in a Crustacean, 458 ; On the Segmental Excretory Organs of certain Freshwater Ostracods, 821 , The Ectodermal Origin of Muscles in Chirocephalus, 929
Carey (M. C.), Stories of the Birds from Myth and Fable, 907
Carleton (H. M), Growth, Phagocytosis and other Phenomena in Tissue Cultures of Fœtal and Adult Lung, 249

Richardson (L.), A Simple Interferometer, 582
Richardson (Prof O. W.), appointed a fellow of King's College, London, 355; Structure in the Secondary Hydrogen Spectrum, 858, and T Tanaka, Regularities in the Secondary Spectrum of Hydrogen, 517, and A F. A Young, The Thermionic Work-functions and Photoelectric Thresholds of the Alkali Metals, 321
Richet (Prof C), E. Bachrach, and H Cardot, The Heredity of Acquired Characters proved by the Displacement of the Thermal Optimum, 286; M. Oxner, and J Richard, Cooked Food and Raw Food in Feeding Fish, 482
Rideal (Dr E. K), A Composite Work on Physical Chemistry, 294, The Reduction Potential of Dicyanquinhydrone, 894
Ridgeway (Sir William), awarded the Huxley medal of the Royal Anthropological Institute, 392
Rigg (Dr G B.), The Pharmacists' Botany, 296
Rimmer (W B), Spectroscopic Parallaxes of 520 Stars of Types F to M, 546
Ringström (Dr), Extinct Rhinoceroses of China, 244
Ritchie (Dr. J), The Control of Mussels in Sea Water-pipes, 661
Roach (Mrs. Muriel), The Physiology of certain Soil Algæ in Pure Culture, 624
Roaf (Prof H E), A Text-book of Physiology, 412
Robb (W), Hybridisation of Oats, 661
Robertson (Principal C. Grant), Sir Thomas H. Holland, Prof. C H Desch, Sir Henry Fowler, Prof. F. W. Burstall, Prof W Cramp, Humanism and Technology and other Essays, 527
Robertson (C. L.), The Problem of Seasonal Forecasting, 245
Robinson (Dr. H.), The *K* Absorption Levels of the Light Atoms: A Correction, 945
Robinson (Prof. R.), Hollins's The Synthesis of Nitrogen Ring Compounds, 636
Robinson (V. C.), appointed assistant to the superintendent of the Museum of Zoology, Cambridge University, 855
Robinson (W.), Proliferation and Doubling in the Flowers of *Cardamine pratensis* L., 358
Robson (G. C.), Seriation and Asymmetry in the Cephalopod Radula, 554
Roche (J.), The Respiration of the Tissues in Avitaminosis and Inanition, 483
Roche (W. L), The Microscopic Anatomy of the Tentacular Sense Organ of *Cardium edulis*, 553
Rockefeller (J. D), gift to the Imperial University Library, Tokyo, 132
Rockefeller, Junr. (J D.), gift to the Metropolitan Museum of Art, New York, 60
Roffo (A F), The Action of the Röntgen Rays on Cholesterol, 323
Rogers (A. F.), Mineralogy of Fossil Bone, 656
Rogers (Dr), Test Objects for Metallurgical Microscopy, 692
Rolleston (Sir Humphry Davy), appointed Regius professor of physic in Cambridge University, 479, Sir Clifford Allbutt, 387
Rollet (A P), An Electrolytic Frequency Meter of Simple Construction, 250
Romieu (M), A New Chemical Reaction of Dry Proteid Materials applicable to Histochemistry, 627
Ronchi (V.), An Interferential Method for the Direct Determination of the Constants and Aberrations of Divergent Optical Systems, 402
Rooke (L), the work of, 988
Room (T G), awarded a Smith's prize, 443
Roosevelt, Junr (Col T), and K Roosevelt, Leading an Expedition through Central and Southern Asia, 848
Rose (Sir Thomas Kirke), The Density of Rhodium, 662
Rosenau (Prof), The Sanitary Survey as an Instrument of Instruction in Medical Schools, 623
Rosenblum (S), A New Determination of the Ratio of the Velocities of the Two Groups of α-Rays emitted by the Active Deposit of Thorium, 930
Rosenhain (Dr. W.), and Miss J McMinn, The Plastic Deformation of Iron and the Formation of Neumann Lines, 786; and A C Sturney, Flow and Rupture of Metals during Cutting, 317
Ross (Dr. G. R.), appointment of, as a Rhodesian research fellow, by the London School of Hygiene and Tropical Medicine, 346
Ross (P A), and D. L Webster, The Compton Effect, 591
Rosset (H.), Phosphorus Chloronitride, 626
Roth (H. Ling), [death], 809; [obituary article], 844
Round (Capt.), and others, Measurement of Radio Signal Strength, 924
Rousselot (Abbé), [obituary article], 164
Row (C. K. Venkata), Relativity referred to a Flat Space-Time, 261
Rowan (W), Relation of Light to Bird Migration and Developmental Changes, 494
Rowell (H. S), Animal Mechanism, 302
Royds, A New Application of the Spectroheliograph, 436
Royds (T.), The Apparent Tripling of certain Lines in Arc Spectra, 178
Russ (Prof. S), The Vision of Nocturnal Animals, 306
Russell (Dr. A.), Automatic Telephony and Teletyping, 103; Oliver Heaviside, 237
Russell (Dr. A. S.), Passivity of Iron and other Metals, 455
Russell (B.), appointed Tarner lecturer in the philosophy of the sciences in Cambridge University, 927; What I Believe, 667
Russell (Dr. B. R. G.), [death], 93
Russell (Rev E. F.), A Student's Reminiscences, 751
Russell (Dr. E. S.), The Study of Living Things: Prolegomena to a Functional Biology, 218; and T. Edser, The Fishery Statistics of England and Wales, 481
Russell (F. S.), Depth-recording with Plankton-nets, 603
Russell (Prof. H. N.), The Distance of the Andromeda Nebula, 436; The Intensities of Lines in Multiplets, 835
Russell (Sir John), elected a corresponding member of the Paris Academy of Sciences, 434; The Place of Science in Rural Life, 995

Russell (L. J.), Science and Philosophy, 70
Rutherford (Sir Ernest), Atomic Nuclei, 505, Disintegration of Atomic Nuclei, 493
Ryan (Prof. H.), and J. Lennon, The Condensation of Aldehydes with Methylethylketone, 178

Sabbatani (L.), Pharmacological Investigations on Iron. VI., 143
Saha (Prof. Meghnad), and Ramani Kanta Swe, Influence of Radiation on Ionisation Equilibrium, 377
Saidman (J.), The Photo-electric Effect produced by Ultra-violet Light in Man, 590
St John (C. E.), and H. D. Babcock, Convection Currents in the Atmospheres of the Sun and Stars, 26
Sakurai (Prof. J.), elected an honorary member of the Royal Institution, 1016
Salauze (J.), The Electrolysis of the Alkaline Acetates in Solution in Methyl Alcohol, 590
Saleeby (Dr.), Natural and Artificial Sunlight in Health and Disease, 956
Salet (M.), The Velocity of Light from the Stars, 813
Salisbury (Dr. E. J.), The Biology of Plants, 9
Salmon (Prof. E. S.), and W. M. Ware, Virus Diseases of the Hop, 993
Salomons (Goldsmid-Stern), (Sir D.), [obituary article], 648
Saltmarsh (Miss M. O.), The Spectra of Doubly and Trebly Ionised Phosphorus (P III and P IV), 517
Sandberg (Dr. C. G. S.), Geodynamische Probleme. I. Isostasie und die ursächliche Einheit von Gebirgsbildung und Vulkanismus. Teil 2, A. Tektonik und Metamorphose, B. Die Widersprüche in der Kontraktionstheorie, 791

TITLE INDEX.

Aberdeen University. award of the Fullerton Research Scholarship to Miss Elizabeth T Geddes, 68; impending lectureship in clinical chemistry, Dr A. Bowman appointed lecturer on the scientific study of fisheries, 176, conferment of the degree of D D on the Bishop of Birmingham, 551, proposed chairs in bacteriology and forestry, approval of plans for a new building for the department of forestry, 820; resignation of Prof. R W Reid, 964

Abrams, The "Electronic Reactions" of, Sir Thomas Horder and others, 789

Absorbing Vapours, Moving, at Great Heights above the Photosphere, L d'Azambuja, 473

Abysmal Submarine Volcanoes, J Thoulet, 887

Acacia Seedlings, Part X, R H Cambage, 555

Acenaphthene, The Direct Hydrogenation and Dehydrogenation of, M N Goswami, 71

Acetylenic Hydrocarbons, Alcohols, and Aldehydes, A General Synthetical Method for the Preparation of ω-Chlorallyl Cyclic Derivatives, and through these, L. Bert, 967

Achromatism in Telescopes, The Choice of Wave-lengths for, Lt.-Col. J W Gifford, 678

Acid-base Titrations and Equilibria of Weak Bases and Acids, Dr I. J Harris, 119, Chlorides, The Catalytic Decomposition of the, A Mailhe, 787

Acidity of Soils, The Action of the Carbonates of the Alkalis and Alkaline Earths on the, V Vincent, 519, produced in Salt Solutions by Sphagnum, Dr. M. Skene and Gladys L Stuart, 605

Acids, Adsorption of, by Purified Silica, Prof J N Mukherjee, 497

Acokanthera spectabilis, The Pharmacological Action of, D F. Morrison, 71

Aconitine, The Alteration of Solutions of, on Keeping, Goris and Métin, 931

Aconitum Anthora and *Aconitum Napellus*, The Chemical Composition of a Hybrid of, A Goris and M. Métin, 895

Acoustic Selection and Radiogoniometry, A Blondel, 694.

Acquired Characters, The Heredity of, proved by the Displacement of the Thermal Optimum, Prof C Richet, E. Bachrach, and H. Cardot, 286

Acyclic δ-diketones, The Preparation of the, E E Blaise and Mlle M. Montagne, 930

Adaptations, The Origin of, Prof T D A Cockerell, 871

Adhesives, Investigations into, 989

Administration, Anthropology and, 666

Adrenaline in Cerebral Anæmia, The Output of, as studied by means of Crossed Circulation, Dr. G V. Anrep and I de B. Daly, 357

Advanced Study and Research in Universities and University Colleges of England and Wales, 479

Aeronautics, The Rotor Ship and, Prof. L. Bairstow, 462

Aeroplane, The word, A E Bostwick, 650

Africa Central, Motor Expedition through French, 884, Tropical, An Educational Policy for, 588

African Glaciers, Beneath, The Humours, Tragedies, and Demands of an East African Government Station as experienced by an Official's Wife, with some Personal Views on Native Life and Customs, Anne Dundas, 453, Tribes, Anthropology of, Brenda Z. Seligman, 866

Afwillite, A New Hydrous Calcium Silicate from Dutoitspan Mine, Kimberley, J. Parry and F. E Wright, 214

Agar-agar, The Absorbing Power of, J. Effront, 250

Age and Area Hypothesis, Evolution and the, A. E Watkins, 675

Agricultural. Economics: Introduction to, Dr. L. C. Gray, 220, The Study of, J A. Venn, 220; Grasses, The Physiology of Reproduction in some, J. W. Gregor, 661, Statistics, International Year-book of, 1923, 442

Agriculture, new scholarships in, 211, Research in, 73, The Function of the Universities in Relation to, Sir Daniel Hall, 785; Tropical, scientific officers in, 449

Air and the Upper Air Temperature up to the Base of the Stratosphere, The Relation between the Source of the, C K. M. Douglas, 787, Electric Discharge Tubes, The Production of "Flashing" in, B. J. Taylor and W. Clarkson, 249; The Refractive Index of, in the Visible Spectrum, between 0° and 100° C., A. Pérard, 251; Upper, International Commission for the Investigation of the, Lt.-Col E. Gold, 781

Airscrew, An Experimental Study of the Vibrations in the Blades and Shaft of an, A Fage, 400

Airship Development in the U S and in Great Britain, 470

Airships, Helium and, R T Elworthy, 158

Albatrosses, the "Soaring" of, Experimental Study of, P Idrac, 532

Alberta, Coal Resources of, E Stansfield, 337

Albino Mouse, The Age of Attainment of Sexual Maturity in the, A S Parkes, 786

Crossley nominated as president of the, 274; The Financial Position of the, Dr A. W. Crossley, 506, Synthesis; Studies in the Investigation of Natural Organic Products, Dr H. Hepworth, 673, Thermodynamics: an Introduction to General Thermodynamics and its Applications to Chemistry, Prof J R Partington, 153
Chemie. allgemeinen, Handbuch der, Herausgegeben von Prof W Ostwald und Prof. C Drucker Band 4. Das Leitvermogen der Losungen, Prof P Walden, Teil I, II, III, 374, anorganischen, Lehrbuch der, Prof K A. Hofmann, Funfte Auflage, 115
Chemische Kristallographie der Flüssigkeiten: Kurze Anleitung zur Synthese und Untersuchung polymorpher und kristallin-flussiger Substanzen, Prof D Vorlander, 6
Chemistry: A School, O J. Flecker, 224; and the Quantum Theory, Prof H S Allen, 452, Applied, 411, Cereal, Modern, D W Kent-Jones, 222, Colloid, an Introduction, with some Practical Applications, J. Alexander Second edition, 634, Colloidal, The Elements of, Prof H Freundlich, Translated by Prof G Barger, 634, Early E J Holmyard, 489, The Story of, Prof J. M Stillman, 489, Fields of Progress in, 32, General A Laboratory Manual in, Prof W Foster, 187, Introduction to, Prof W Foster, 187, House, The Proposed, W J U. Woolcock, 506, in India 175, Dr M O Forster, Prof J F Thorpe, 281, in the Service of the State, 544; Inorganic A Text-book of, Edited by Dr J. N. Friend Vol 2 The Alkali-metals and their Congeners, Dr A J Walker Vol 7, Part I. Oxygen, Dr J. N Friend and Dr D F Twiss, 11, and Theoretical, A Comprehensive Treatise on, Dr. J W Mellor, Vol 5, 80, Institute of, annual meeting, election of officers, 347, of Flour Milling, The, 222; Organic, Practical, Prof J B Cohen Third edition, 189, Pedological, U Pratolongo, 695, Physical: A Composite Work on, Dr E K Rideal, 294, A System of, Prof W C McC Lewis Third edition. In 3 vols Vol 3 Quantum Theory With certain Appendices by J Rice, A. M'Keown, and R O Griffith, 452, A Treatise on, A Co-operative Effect by a Group of Physical Chemists Edited by Prof H S Taylor 2 vols, 294
Chenopodium Oil in the Treatment of Hookworm, Drs W G Smillie and S B Pessoa, 583
Chilka Lake, Copepoda of the, Major R B S Sewell, 438
China Botanical Exploration in, 996, Bronze in, A. Vayson de Pradenne and G Chesneau, 394, England and, The Case for Co-operation between, Dr R P. Scott, 273, Extinct Rhinoceroses of, Dr Ringstrom, 244, Indemnity (Application) Bill, The 390, Co-Ching Chu, 543, Neolithic Agricultural Implements from, P Lacent and G Teilhard de Chardin, 922, Northern, Palæolithic Industry in, de Chadin and Lacent, 62, The Science Society of, 920
Chinese, Anthropology of the, W W Cadbury, 437
Chirocephalus, The Ectodermal Origin of Muscles in, H G. Cannon, 929
Chlorine, The Action of, on a-pinene, G Brus, 967
Chloroform, The Fixation of, by the Central Nervous System and the Peripheral Nerves, M Nicloux and A Yovanovitch, 142
Chlorophyll Spectra, J Wlodek, 439
Cholesterol in the Animal Organism, Origin and Destiny of, Part XIV, J. W. Fox and J A Gardner, 249
Cinchona and Ipecacuanha in Burma, 135, Insect Pest, A, 170
Cinematography, Colour, C Friese-Greene, 923
Circle, The Graduation of the, J. A Smith, 556
Circular Cylinders, The Motion of, in a Viscous Fluid, R. A Frazer, 401
Circulation, Central and Reflex Regulation of the, Dr G. V. Anrep and Prof. E. H. Starling, 357
Citrus Fruit and Scurvy, Prof. W. A Osborne, 194
Civil Engineers, Institution of: awards of the, 686, Senatore G. Marconi elected an honorary member of the, 168; Sir William H Ellis elected president of the, 811
Clausilia bidentata (Strom) and *Cl. cravenensis* (Taylor), W. E. Alkins, 285
Clifton College, new science buildings of, 918

Climate and Plant Distribution in the Light of the Fossil Record, Prof. A. C. Seward, 394
Climates, Ancient, papers on, 990
Clockmaking, Past and Present, with which is incorporated the more important portions of "Clocks, Watches and Bells," by the late Lord Grimthorpe, relating to Turret Clocks and Gravity Escapements, G. F. C. Gordon, 418
Cloud Forms, B. C Kadel, H C. Frankenfield, and F. G. Tingley, 30
Clouds and Forecasting Weather, Prof. E. van Everdingen, 657
Coal: Mining, Consumption of Power in, Prof A. J. Hoskin and T. Fraser, 619, Resources of Alberta, E Stansfield, 337, Tar, The Constituents of, Dr P. E Spielmann, 411, Seams, the Survey and Classification of, 989
Cobalt, T H. Gant, 888
Coco-nut Pearls, Nature and Origin of, Dr F W. T Hunger, 138
Coconuts, Variation in, H W Jack, 687
Codeine and Thebaine, The Constitution of, J M Gulland and R Robinson, 625
Comadai area, Victoria, Geology of the, with Special Reference to the Limestone Series, A H. Coulsen, 287
Coke and its By-products, 991
Colchicum montanum, Linn., C C Lacaita, 178
Coli Bacillus, The Pathogeny and Conditions of Maintenance of the, H Vincent, 482
Collembola from Mesopotamia, Some, J. M Brown, 625, from Southern New Zealand, Prof G. H Carpenter, 859
Colloid Chemistry A Proposed American National Institute for Research in, 469, an Introduction, with some Practical Applications, J Alexander Second edition, 634
Colloidal Chemistry, The Elements of, Prof H Freundlich Translated by Prof G. Barger, 631; Suspensions On the Distribution of Particles in, W. W. Barkas, 481; The Law of Distribution of Particles in, the Specific Volume of a Gamboge Suspension, J R H Coutts, 481
Colloïdes, Les, J Duclaux. Trois édition, 634
Colloids, Protective, J. Alexander, 172
Colonial governments and scientific research, 95
Colostrum and Milk, The Bacteriolytic Power of, J and Mlle M Bordet, 34
Colour. -change, The Physiology of, Prof F W. Gamble, 147, Fatigue in the Eye, Dr F W Edridge-Green, 206, Mixture Problems, The Geometrical Solution of, J. Guild, 893, Photography. Direct, A Hoffmann, 133, The "Jos-Pe" process of, 619, Problems, Modern, Dr L C Martin, 778, The Magic of, S Culin, 958
Comet: A New? 26, Tail Spectrum, The, and Deslandres' First Negative Group, H B Lemon, 591
Comets, 508, 546, 616, 653, 776, 813, 850
Commonwealth Fund, New York, award of fellowships by the, 892
Community, Science and the: 4, Dr. G. Martin, 122
Compton Effect, The Profs D L Webster and P. A. Ross, 51, P A Ross and Prof. D L Webster, 591; and Tertiary X-radiation, Y H Woo, 823
Compton and Duane Effects, The, Prof. G. E M. Jauncey, 456
Conductivity in Solution and Constitution, G. N. Quam and J. A Wilkinson, 960
Conductors, Metal-clad Enclosure of, H. W. Clothier, 207
Conicoids, The Classification of, by their Generators, H. G Green, 358
Coniferæ, An Endotrophic Fungus in the, Dr. M C. Rayner, 14
Conifers, Resin Canals in the Evolution of the, E. C. Jeffrey, 591
Consciousness, Classification of, Dr. C. S Myers, 98
Continental Drift, Prof J. W. Gregory, 255
Continents, and Oceans, The Origin of, Prof. A. Wegener. Translated by J. G. A Skerl, 255; The, and the Origin of the Moon, Dr. R. H. Rastall, 646; The Origin of the, Dr. A. Holmes, 873
Contoured Maps, a New Apparatus for the Automatic Construction of, by Photographic Restitution, J. Prédhumeau, 70
Contractile Vacuole, The Nature of the, Prof J. B. Gatenby and Miss S D King, 157
Convective Equilibrium, R. M. Deeley, 51
Copenhagen, The Botanic Garden, 210
Copper: Crystals, The Production of, Dr. W. P. Davey, 203; Sulphate, The Action of Solutions of, on Mildew, M and Mme G. Villedieu, 106, The Catalytic Action of, Part II, F H Constable, 321, Part V, W. G. Palmer and F H. Constable, 321; The Electrical Resistivity of, The Effects of certain Elements on, A L. Norbury, 662
Corbiculæ, New, from Uruguay, W B. Marshall, 135
Cordierite-anthophyllite Mineralisation at Blue Hill, Maine, etc., W Lindgren, 590
Correns. Carl, Gesammelte Abhandlungen zur Vererbungswissenschaft aus periodischen Schriften, 1899–1924, 827

CORRESPONDENCE

Accelerometer, The Jet-wave, Dr J Hartmann, 872
Achromatism in Telescopes, The Choice of Wave-lengths for, Lt.-Col J W Gifford, 678
Acid-base Titrations and Equilibria of Weak Bases and Acids, Dr L J Harris, 119
Acidity produced in Salt Solutions by Sphagnum, Dr M Skene and Gladys L. Stuart, 605
Acids, Adsorption of, by Purified Silica, Prof. J N. Mukherjee, 497
Adaptations, The Origin of, Prof T. D A Cockerell, 871
Age and Area Hypothesis, Evolution, and the, A E. Watkins, 675
Albatrosses, The "Soaring" of, Experimental Study of, P Idrac, 532
"Alumen," The Identity of, in Pliny's Natural History, K C Bailey, 764
Aluminium, On the Absorption Spectrum of, Kanakendu Majumder and Naline Kanta Swe, 459
Ammonia, Losses of, from Soil by Volatilisation, G. R. Clarke and C. G T Morison, 423
Amœba, The Life-history of, Dr. Monica Taylor, 606
Animal Mechanism, H. S Rowell, 302
Ankylostomiasis, Diagnosis of, Dr. M. Khalil; Lt.-Col. Clayton Lane, 762
Anomalous Dispersion in the Field of X-Rays, Dr. E. Hjalmar and Prof M Siegbahn, 85
Antirachitic Substances, Ultra-violet Radiations and, Prof J. C. Drummond and T A Webster, 837
Anti-Relativity Experiment, The Reported, Sir Oliver Lodge, 460
Argon, Spectra of, and Ionised Potassium, On a Connexion between the, T. L de Bruin and Prof P. Zeeman, 116; The Discovery of, Dr. W. W. Travers, 121
Arsenic in Oysters, Dr H E. Cox, 51
Astrophysics without Mathematics, Prof. H. Dingle; Prof. E. A. Milne, 193
Atmospheric Electric Transmission, Sir Joseph Larmor, 566
Atom, The Electronic Configuration of the, Paramagnetism and, Dr. L. C. Jackson, 981
Atomic Nuclei, Disintegration of, Sir Ernest Rutherford, 493
Auroral Green Line, The, Prof. J. C McLennan, 382, 607
"Australopithecus," The word, and others, Prof. R. A. Dart, 875; Dr. F. A. Bather, 947
Avena, Chromosomes in, C. L. Huskins, 677
Ball Lightning Phenomena, B. Davies, 640
Band Spectra, Intensities of, G. H Dieke, 875
Benzene: Centenary, The Faraday, Prof. H. E. Armstrong, 870; The Discovery of, Dr. E. H. Tripp, 909
Biographical Byways: Dr. S. P. Langley, Dr. C. G. Abbot, 455
Bioluminescence, Dr. J. Weir French, 944
Bird Migration and Developmental Changes, Relation of Light to, W. Rowan, 494
Blood Pressure in Early Life, Dr. P. Stocks, 302; The Reviewer, 302

Browning, Robert, as an Exponent of Research, G. W. Lamplugh, 298, Dr. H R Mill, 424, Prof. W R. Whitney, 607
Bushmen Rock Figures, Sir Flinders Petrie, 534
Catalysis, Heterogeneous, Prof. J. R. Partington, 534
Cathode Rays in Aluminium, The Absorption of, B F J. Schonland, 497
Celluloid, Molecular Dimensions of, H Garnett, 51, F. Sproxton, 158
Cetacean, A Stranded, H C. Chadwick, 801
Citrus Fruit and Scurvy, Prof W A Osborne, 194
Coal Resources of Alberta, E Stansfield, 337
Colour-matching, Photo-electric Cells for, Sir J E Petavel, 875
Community, Science and the, Dr. G Martin, 122
Compton: Effect, The, Profs D L Webster and P A. Ross, 51; and Duane Effects, The, Prof G E M Jauncey, 456
Coniferæ, An Endotrophic Fungus in the, Dr M C Rayner, 14
Continents, The Origin of the, Dr A Holmes, 873
Contractile Vacuole, The Nature of the, Prof J B. Gatenby and Miss S. D King, 157
Convective Equilibrium, R. M Deeley, 51
Cresswell Caves, Late Palæolithic Art in the, Prof W Boyd Dawkins, 336, Prof W J Sollas, 420, Engravings, The, J. W Jackson, 874
Crisp Collection of Microscopes, The, Dr R T Gunther, 265
Crustacean, Ectodermal Muscles in a, Dr H G Cannon, 458
Crystal Structure, Molecular Symmetry in, J H Smith, 334
Crystals and Lenses of Fats on the Surface of Water, The Behaviour of, A P Cary and Dr. E K Rideal, 457
Curious Survival, A, Sir Oliver Lodge, 678
Dana Expedition, Hydrography of the, Dr J. N Nielsen, 529
Deep Sea Tides, Method of Measuring, Dr H Pettersson, 639
Depth-recording with Plankton-nets, F S Russell, 603, R. Appleyard, 870
Diamagnetic Orientation, E C Stoner, 302
Dinosaur Region in Tanganyika Territory, The, Sir Sidney F. Harmer, 638
Duane, Compton and, Effects, The, Prof G E M Jauncey, 456
Dutch Pendulum Observations in Submarines, Sir G P Lenox-Conyngham, 116
Earth's Rotation, The Effect of the, on the Velocity of Light, Sir Joseph Larmor; Dr J H Jeans, 638
Ectodermal Muscles in a Crustacean, Dr H G Cannon, 458
Electrical Drift in the Air, The Positive, Dr W C Reynolds; Dr. C. Chree, 531, Dr. W C Reynolds, 836
Electricity in Curved Space-time, G Y. Rainich, 498
Electrolytes, The Action of Silica on, A F Joseph, 460
Ether: and Matter and Relativity, Sir Oliver Lodge, 419, and the Metaphysical Mind, F F P B, 533, -drift and the Relativity Theory, Prof A S Eddington, 870, The Exploded, Sir Joseph Larmor, 419
Evolution: and the Age and Area Hypothesis, A. E Watkins, 675; in the United States, The Teaching of, Prof. B. Cunningham, 678
Faraday; A Course of, Prof. H E. Armstrong, 568; Benzene Centenary, The, Prof H E. Armstrong, 870
Fish, The Growth of, J. Gray, 676
Fishing-nets, Mosquito-nets, and Tent Fabrics, The Preservation of, Dr. W. R. G. Atkins, 761
Fog, London, of January 11-12, 1925, Dr J S. Owens, 121
Fossils and Leonardo da Vinci, Dr. P E Spielmann, 763
Frog, Abnormal Anterior Abdominal Veins in the, Three Cases of, Dr. Nellie B. Eales, 606
γ-rays: Effective Wave-lengths of, Prof. J. A Gray, 13, Scattering and Absorption of, Prof. J. A. Gray, 86
Graphitic Conduction in Conjugated Chains of Carbon Atoms; a Contribution to Armstrong's Theory of Chemical Change, Prof. T. M. Lowry, 376
Growth-ratios and their Significance, Constant Differential, Dr. G. F. Bidder, 155
Hafnium Oxide in Tungsten Filaments, J. A. M. van Liempt, 194
Hearing, The Theory of, Prof. E. W. Scripture, 228; G. Wilkinson, 379
Helium: Chemical Combination of, Dr. E H. Boomer, 16; Double Impacts by Electrons in, G. Glockler, 909, E. G. Dymond, 910
Helmholtz's "Physiological Optics," The Translation of, Alice Everett, 424
Herring Fishery, Salps and the, Prof. W C McIntosh, 911
High Tension Electric Fields, Effects of, upon the Discharge of Locomotive Gases, Dr P. L. Mercanton, 874
Huxley's Contributions to the Study of the Invertebrat., Prof E. W MacBride, 838
Hydra and the Tadpoles, Prof S J. Hickson, 802
Hypothecate, One who has done so, 912
Incubation, Artificial, C J P. Cave and T V Jones, 49
Indian Kala Azar Commission, Lieut.-Col S. R Christophers, 421
Insects, Genital Ducts of, Homologies of the, Hem Singh Pruthi, 763
Intensities of Lines in Multiplets, Prof. H N Russell, 835
Intermetallic Reactions in a Lead-base Bearing Metal, Prof O W Ellis, 382
Ionisation Equilibrium, Influence of Radiation on, Prof Meghnad Saha and Ramam Kanta Swe, 377, Dr J Woltjer, Jr, 534
Iron and Other Metals, Passivity of, Dr A S Russell, 455, and Steel, Specific and Latent Heats of, A Mallock, 14
J-Transformation of X-rays, Spectroscopic Evidence of, Dr S R Khastgir and W H Watson, 604
Jet-wave Accelerometer, The, Dr J Hartmann, 872
Jurassic Insects, A New Locality for, Prof T. D A Cockerell, 947
K Absorption Levels of the Light Atoms, The A Correction, Dr H Robinson, 945

Taungs Skull, The, Dr. R. Broom, 569, Prof. W. J. Sollas, 908
Thallium Vapour, On the Resonance Radiation from, Prof. A. L. Narayan and K Rangadhama Rao, 534
Thorium Disintegration Products, High Energy γ-Ray from, D. H. Black, 226
Tides, Deep Sea, Method of Measuring, Prof. R. W. Wood, 497
Touch and Sight *v.* The Microscope in Wool Classing and Sorting, Prof. A F. Barker, 226
Trinidad, Rainfall Correlations in, W. R. Dunlop, 192, 802
Tungsten, On the Spark Spectrum of, in a Helium Vacuum Arc, Prof. H. B. Lemon, 802

Tuning Fork, the Frequency of a, A Method of Determining, Prof J. B Seth, 641
Uganda, Petroleum in, E. J Wayland, The Writer of the Note, 980
Ultra-Violet Radiation, Dosage with, Dr H D. H. Drane, 945; Radiations and Antirachitic Substances, Prof. J. C. Drummond and T. A Webster, 837
United States, The Teaching of Evolution in the, Prof B Cunningham, 678
Vernier Wireless Time-signals, S K Banerji, Dr A C D Crommelin, 912
Verse, The Nature of, Principal Egerton Smith, 15
Viscous Fluid Motion, Instability of, Major A R Low, Capt. D Brunt, 299
Water Vapour, The Structure of the so-called Ultra-violet Bands of, G H Dieke, 194
Waterspouts, Formation of, C S Durst, 676
Wegener Hypothesis, Permo-Carboniferous Glaciation and the, Prof. A P. Coleman; Prof J W. Gregory, 602
Wegener's Hypothesis and the Distribution of Micro-Lepidoptera, E Meyrick, 834
Whelk (*Buccinum undatum*), An Amphoteric Substance in the Radula of the, C F A Pantin and T H Rogers, 639
Wind. Short-period Variations of the, N K Johnson, 263; Visible, Catherine O Stevens, 764
Wireless Signals, The Solar Eclipse of January 24 and, Dr. W. H Eccles, 260; Time signals, Vernier, S K Banerji, Dr A C D Crommelin, 912, Waves, Local Reflection of, from the Upper Atmosphere, Prof E V Appleton and M A F Barnett, 333
Wool Classing and Sorting, The Microscope in, Touch and Sight in, Prof A F Barker, 226
X-radiation, Scattered, Total Intensity of, O K DeFoe and W W Nipper, 607
X-radiations, Superposed, The Coherence of, Prof C G Barkla and Gladys I Mackenzie, 942
X-rays, *J*-Transformation of, Spectroscopic Evidence of, Dr. S R. Khastgir and W H Watson, 604
Zeeman Triplet on a Quantum Basis, On the generally accepted Explanation of the, Prof W M Hicks, 978
Zirconium and Hafnium, The Atomic Weights of, Prof G Hevesy, 335

Coryndon Memorial Fund, The, 987
Cosmology, Relativity and, 408
Cotton Cellulose Chemistry and Technology of, Dr J C Withers, 757, its Chemistry and Technology, A J Hall, 757, Growing, Climatic Conditions for, E E Canney, 438; Industry, Science and the, Dr A W Crossley, 166, Material, Mildewed, Methods of Examination of, T B Bright, 553, Queensland Ratooned, F Summers, 171, Ratoon, J Templeton, 993; Research, The Microscope in, F Summers, 553
Crane-flies, Fossil, from South America, G R Wieland, 351
Cratægo-mespilus Asmersii and *Cratægo-mespilus Dardari*, On the Structure of the Leaves of, Prof F E Weiss, 859
Cresswell Caves, Late Palæolithic Art in the Prof W Boyd Dawkins, 336, Prof W J Sollas, 420, Crags, Derbyshire, Excavations at, A L Armstrong, 658, Engravings, The, J W Jackson, 874
Crichton Royal Institution, Report of the, 508
Crime and Insanity, Dr. W. C. Sullivan, 414
Crisp Collection of Microscopes Sale of the, 241, 311, Dr. R. T. Gunther, 265
Critical: Potentials, Prof K T Compton and Dr F L Mohler, 443; Tables, The International, 32
Croonian Lecture, R Magnus, 965
Crop Production, The Chemistry of, Prof T. B Wood Second edition, 259
Crops, Control of Disease in, L R. Tehon, 815
Crossed Circulation, A New Method of, Dr G V Anrep, 357
Crustacean, Growth Stages of a, Mrs E W Sexton, 783
Crystal: Formation, Dr T. V. Barker, 208, Powder Analysis, A Focussing Method of, by X-rays, J. Brentano, 589; Structure, Molecular Symmetry in, J. H. Smith, 334
Crystalline Lens: Investigations on the, Dorothy Adams, 553; The Chemical Composition of the Normal and Pathological, H Labbé and F Lavagna, 823
Crystals and Lenses of Fats on the Surface of Water, The Behaviour of, A P Cary and Dr. E K Rideal, 457; Single Metallic, Physical Properties of, Dr P. W Bridgman, 136, The Effect of, on X-rays, Diffraction Gratings constructed to Illustrate, Prof. W. L Bragg, 482, The Formation of, Model illustrating, Prof W. L Bragg, 482; The Photo-electric Primary Current in, B Gudden and R Pohl, 99; The Structure of, Dr W G. Wyckoff, 6, The Study of, Prof T M Lowry, 6
Cugnot, Nicolas Joseph, bicentenary of the birth of, 270
Cultural Impacts, The Historical Succession of, upon South Africa, Prof R A Dart, 425, 432
Currents, Extremely Small, the Measurement of, A Method of Comparison permitting, B Szilard, 554.
Curtis's Botanical Magazine, 351
Cyanohydrins, Carboxylic Acids and Phenols, A Comparison of some Properties of, Prof A Lapworth, 625
Cycads, The Origin of the, Prof C J Chamberlain, 316
Cyclohexenols, The Preparation of, by the Catalytic Dehydrogenation of Cyclohexanediols, J B Senderens, 626
Cylinder Boring Machine, The Early History of the, Forward, 24
Cyprinidæ, The Anatomy and Physiology of the Air-bladder and Weberian Ossicles in, H M Evans, 285
Cytochrome On, a Respiratory Pigment common to Animals and Yeast, D Keilin, 446
Cytological Technique, Some Modifications of the Osmic Acid Methods in, R J Ludford, 280
Cytology An Introduction to the Study of, Dr L Doncaster Second edition, 224, General, a Text-book of Cellular Structure and Function for Students of Biology and Medicine, R Chambers and others Edited by F V Cowdry, 185, Modern Views on, Prof J B Gatenby, 185

Dacca, An Experiment in University Education in India, 842
Daly, Charles P, Gold Medal, awarded to K Rasmussen, 132
Dana Expedition, Hydrography of the, Dr J N Nielsen, 529
Danish State Serum Institute, Grant to the, by the International Health Board of the Rockefeller Foundation, 275
Darwinism, The Proscription of, 485, 683
Darwinist, The Religion of a Conway Memorial Lecture delivered at South Place Institute on March 26, 1925, Sir Arthur Keith, 667
Datiscine, The Glucoside of *Datisca cannabina*, C. Charaux, 931

Dielectric Absorption and Power Losses, A contact theory of, L. Hartshorn, 822
Diffusion: The Displacement of Acids by, E. Demoussy, 967, Viscosity, and External Pressure, Velocity of, E. Cohen and H. R. Bruins, 476
Digestive Hæmoclasia and the state of Neuro-vegetative Tonus, P. Widal, P. Abrami, Diaconescu, and Gruber, 626
Dinosaur Region in Tanganyika Territory, The, C. W. Hobley, 573, Sir Sidney F. Harmer, 638
Dipnoi, The Cranial Roofing-bones in the, Prof. E. S. Goodrich, 178
Direct-current Generator, A new, giving 500,000 volts, d'Arsonval, J. Perrin, 999
Discovery, R.R.S., The Expedition of the, 950, 953
Dissociative Equilibrium in an external field of Force, Prof. E. A. Milne, 70
Distillation du bois, Prof. G. Dupont; Prof. J. Reilly, 153
Divergent Optical Systems, An Interferential Method for the Direct Determination of the Constants and Aberrations of, V. Ronchi, 402
Doctor's Oath, The: an Essay in the History of Medicine, W. H. S. Jones, 372
Doldrums of the North Atlantic, The, C. S. Durst, 351
Dorypterus, The Permian Fish, E. L. Gill, 214
"Double Square, The"—a new Optical Appliance based upon the "Optical Square," J. W. Gordon, 893
Downtonian Fauna of Norway, The, I. Anaspida, with a Geological Introduction, Prof. J. Kiær, 124
Dresden Technische Hochschule, Dr. A. Heilmann nominated a professor in the, 399
Drought-Resistance of Plants, N. A. Maksimov, 922
Duane, The Compton and, Effects, Prof. G. E. M. Jauncey, 456
Dublin University, gift to, by Prof. J. M. Purser, 211
Durham University, Dr. T. Alty appointed professor of physics in Saskatchewan University; Appointments in, 997
Düsseldorf Medical Academy, Dr. F. Hildebrandt offered the chair of pharmacology in, 248
Dussertite, a New Mineral, Description of, J. Barthoux, 359
Dutch Pendulum Observations in Submarines, Sir G. P. Lenox-Conyngham, 116
Dye Stuffs: in Concentrated Solutions, The Fluorescence of, Dr. S. J. Wawilow, 852; Industry Development Committee, Dr. E. F. Armstrong and H. Sutcliffe-Smith appointed members of the, 956
Dyes, British-made, 94, 95

Early: Chellean: Flint Implements from the Cromer Forest Bed of Norfolk, Further Discoveries of, J. Reid Moir, 518; Hand-axes, Exhibition of, at Ipswich, 349; Man and his Predecessors, Dr. A. Hrdlicka leading a survey of the field of, 773

Earth: Metal Resources and the Constitution of the, 914; Movements in California, Dr. A L Day, 886, The Cooling of the, L. H Adams, 98, Dr H Jeffreys, 876; The Electrical Charge of the, Dr C Ramsauer, 29; The Ovoid Form of the, The Metric Proof of, C. Gorceix, 286
Earthquake: in Cornwall, 241; in Japan, A Severe, 847, -proof Buildings, H M Hadley, 545
Earthquakes: and Geology, Dr C Davison, 112, British, A History of, Dr C Davison, 524
Earth's: Electric Field, The, and Vertical Potential Gradient, S. Ray, 823, Rotation, The Effect of the, on the Velocity of Light Profs. A A Michelson and H G. Gale, 566, Sir Joseph Larmor, Dr J H Jeans, 638
Earwigs, Dimorphism in, D M Diakonov, 777
East: Africa: Among the Natives of, 453, Birds and Butterflies of, Dr V. G L van Someren and others, 992; Education in, Dr T J Jones, 753, Science and Administration in 37, Prof J W Gregory, 753, African Commission, Report of the, 753
Eastman Kodak Company, Research Laboratory of the: Abridged Scientific Publications from the, Vol 6, 1922, 12, The Abridged Scientific Publications of the, 26
Échinodermes des mers d'Europe, Les, Prof R Koehler, 796
Echinoderms, Experiments on, H C Chadwick, 548
Echinoid, A New Devonian, A O Thomas, 584
Echo Sounding, 689
Economic Research in Tropical Development, W R Dunlop, 241
Ectodermal Muscles in a Crustacean, Dr H G Cannon, 458
Edinburgh University resignation of Sir Harold J Stiles, the late Sir Archibald Geikie's gifts to the geology department, 176, resignation of Sir Richard Lodge, W Oliver appointed professor of the organisation of industry and commerce, the Cameron Prize awarded to Prof. R. Magnus, resignation of W L Ferrar, 320; Dr J. Fraser appointed regius professor of clinical surgery, K G Fenelon appointed lecturer on railway economics, grant from the Forestry Commission, 479, forthcoming conferment of honorary degrees, 515, appointments, 693, resignation of W. M'Clelland, Major W S Patton to investigate kala azar in North China, K P Brown appointed lecturer in clinical surgery and Dr G Buchanan lecturer in bacteriology, 856
Education, Board of, Sir Aubrey Symonds appointed permanent secretary of the, 211
Educational Labour Colonies, the organisation of, Capt J. W Petavel, 623
Edward, King, the Seventh College of Medicine, Singapore, gift to the, by the Rockefeller Foundation, 991
Egg: Definition of an, 433, Fragments, The Development of, Profs. C Taylor and D H. Tennent, 992
Egypt and the Sudan, The Water Supply of, 247
Egyptian, Mathematics, Prof D'Arcy W Thompson, 899, 935, Mummies, Prof G Elliot Smith and W R Dawson; Dr. H. R. Hall, 113, Survival, An, Miss Winifred Blackman, 851
Einstein's Theory of Relativity, Prof Max Born Translated by H. L. Brose, 408
Elastic Stability, On the Theory of, W. R Dean, 401
Elasticity, Applied, Dr J. Prescott, 373
Electric: Equilibrium at Boundary Surfaces, Conditions of, Volta Effect, E. H. Hall, 823, Forces and Quanta, Dr. J. H. Jeans, 346, 361; Generating Sets, Small, employing Internal Combustion Engines, W Wilson, 417; Light, Charging for, G Wilkinson and R McCourt, 579; Transmission, Atmospheric, Sir Joseph Larmor, 566; Waves, around the Earth's Surface, The Transmission of, Prof. H M Macdonald, 401; Condition that the Ratio of the Intensities of the transmitted and reflected, at the interface between two Media is independent of their Plane of Polarisation, Prof. H. M. Macdonald, 999
Electrical: Counter, The action of the, K G. Emeléus, 966; Drift, The Positive, in the Air, Dr. W. C. Reynolds, 836; Engineers, Institution of, award of premiums, 775; Forces and Quanta, Dr. J. H. Jeans, 240, Installation, The Automatic Regulation of the Power of an, M Doloukhanoff, 70; Instruments, 831; Machinery and Control Diagrams, T Croft, 454; Measuremonts, A System of, F. E Smith, 446, Measuring Instruments, Dr C V. Drysdale and A. C. Jolley, Part 2, 831
Electricity, and Magnetism, a Text-book for Colleges and Technical Schools, Profs W S. Franklin and B. MacNutt, 11; Atomic? Is, Prof Ehrenhaft, 688, in Curved Space-time, G Y Rainich, 498
Electrolytes, Conductivities of, O Scarpa, 99, The Action of Silica on, Dr. A. F Joseph, 460
Electrolytic Frequency Meter of Simple Construction, An, A P Rollet, 250
Electro-magnetic Waves, The Absorption of, by Ice, J. Granier, 106, magnets, The Construction of, P. Villard, 141
Electromagnetism, A New Law of, Ferrier and L Besnerais, 554
"Electronic Reactions of Abrams," The, 789
Electrons Free, The Number of, with a Metal, E. H. Hall, 590, Secondary, produced by hard X-rays in Light Elements, H Fricke and O Glasser, 179, The Passage of, through Small Apertures, J. F. Lehmann and T H Osgood, 999
Elements of Different Valencies, Solid Solutions between Compounds of, G Bruni and G R Levi, 402, The Relative Abundance of the, Astrophysical Data bearing on, Cecilia H Payne, 895, Two New, 954
Elephants, Extinct, in England, Dr Sandford, 993
Elliot, Daniel Giraud, Medal, the, awarded to Abbé H. Breuil, 616
Empire, Cotton Growing Corporation, Report of the, 390, 955, Textile Conference, Report of the, 392
Emulsoids, The Influence of, upon the Rate of Dissolution of Zinc in Solutions of Lead, Nickel, and Copper Salts, Dr J N Friend and J S Tidmus, 662
Enamelled Wires, the Insulation of, A Recording Apparatus for the Control of, J. Cathala, 447
Encke's Comet, G A Tikhov, 314
Endocrine Organs and Secretion, 293 The, an Introduction to the Study of Internal Secretion, Sir E Sharpey-Schafer Second edition Part I, 293
Energy of the Universe The Fate of the, a Tangled Skein, 405
England and China, The Case for Co-operation between, Dr R P Scott, 273
English Channel, Evaporation and Temperature Changes in the, H W Harvey, 778
Ensilage, The Practice of, Amos, 474
Eotvos Torsion Balance, An Improved Model of the, L. Oertling, Ltd, 585
Epididymis, Cell Organs during Secretion in the, R. J. Ludford, 893
Equilibria, Heterogeneous, J A V Butler, 354
Equilibrium, A New Principle of, G N Lewis, 895
Erlangen University, Prof R Pummerer appointed professor of chemistry in, 399
Eros, The Opposition of, in 1931, Dr Watt, 205
Ethane in Fire-damp from the Mines de Gagnières, The Presence of, P Lebeau, 71
Ether: and Matter and Relativity, Sir Oliver Lodge, 419; and Reality, Sir Oliver Lodge, 203, 272, 347, 433, 505, and the Metaphysical Mind, F F P. B, 533, -drift and the Relativity Theory, Prof A. S. Eddington, 870, of Space and its Functions, The, Sir Oliver Lodge, 59, Oxides, General Method for the Preparation of the, H. Wuyts, 590, The Entanglement of the, and the Aberration of the Stars, A. Metz, 519, The Exploded, Sir Joseph Larmor, 419
Euphorbiaceæ, Characteristics of some Oils from, P Gillot, 895
Euphrates Valley, Early Art in the, Dr. L. Legrain, 886
Europe. Vol. I: The Peninsula. Edited by B C Wallis. (Stanford's Compendium of Geography and Travel, New Issue), 327
Evans, Lewis, Collection of Historic Scientific Instruments, The, 651, 783
Everest Expedition, Exhibition of Photographs, etc., from the, 167

Evolution. and the Age and Area Hypothesis, A. E. Watkins, 675; Population and, 406; since Darwin, The Theory of, Prof. E W MacBride, 52, 89, The Teaching of, in the United States Prof. B Cunningham, 678; 987
Explosion Motor of 1806 of the Brothers Niepce, Reconstitution of the, P Clerget, 662
Explosive Wave, The Propagation of the, P. Laffitte, 141
Extra Pharmacopœia, The, of Martindale and Westcott. Revised by Dr W H Martindale and W Wynn Westcott. Eighteenth edition, in 2 vols Vol I, 869

Factorisation, On a New Method of, D N Lehmer, 591
Falkland Islands, The, V F Boyson, with Notes on the Natural History, by R Vallentin, 940
Faraday A Course of, Prof H E. Armstrong, 568; and his Contemporaries, Prof E Cohen, 1014, as a Chemist, Sir William J Pope, 953, 1002, Benzene Centenary, The, Prof H E Armstrong, 870, 1010, Medal of the Institution of Electrical Engineers, The, awarded to Sir J J Thomson, 168
Far Eastern Association of Tropical Medicine, Transactions of the Fifth Biennial Congress held at Singapore, 1923, edited by the Hon Dr A L Hoops and Dr J W Scharff, 830
Farm Accounting, Profs E. L Currier, N J Lennes, and A S Merrill, 220, Accounts, C S Orwin, 220, Costing, A Short System of, H R J Holmes, 220
Fat Globules, J Golding, 446
Fatty Acids, The, G Friedel, 482
Ferns, Variegation and Leaf-structure in, The Genetics of, Miss I Andersson, 929
Ferromagnetic Ferric Oxide, R. Chevallier, 967
Ferrous Metals, The Electrolytic Corrosion of, W M Thornton and J A Harle, 481
Fertilisers and Feeding Stuffs, appointment of an advisory committee on, 60
Field of Force near the Neutral Point produced by two equal Coaxial Coils, with Special Reference to the Campbell Standard of Mutual Inductance, On the, R M Wilmotte, 401
Fiji Islands The Origin of the Art of Stencilling in the, H Balfour, 34, 814
Films, The Investigation of the Properties of Thin, by Means of X-rays, Sir William Bragg, 266
Finger Prints, Heredity in, Mlle Kristine Bonnevie, 27
Fiord Countries, The Climatic History of the, C E P Brooks, 68
Fireball, The Brilliant, of Easter Sunday, W. F Denning, 616
First Five Thousand, The, Dr Marie Stopes, 543
Fish. Feeding, Cooked Food and Raw Food in, Prof. C. Richet, M Oxner, and J Richard, 482, Showers of, C A Silberrad, F. Richards, 883, The Growth of, J. Gray, 670, Traps in Eastern Asia, H Balfour, 509
Fishery Board for Scotland, Forty-second Annual Report, being for the year 1923, 209, Scientific Work of the, Prof W C McIntosh, 209, Statistics of England and Wales, E S Russell and T Edser, 481
Fishing-nets, Mosquito-nets, and Tent Fabrics, The Preservation of, Dr W R G Atkins, 761
Fison Memorial Lecture, The, Sir J. J Thomson, 774
Fitzgerald Contraction, Influence of the, upon Distance Measurements and Clock Times, Rev. H C Browne, 70
Flavone extracted from the Red Leaves of *Prunus Pissardi*, The Combined Action of Hydrochloric Acid and Metallic Sodium on the Reddening of a, S Jonesco, 930
Flax Plant, A Genetical Study of the, Adelaide G Davin and G O Searle, 922
Florida, Archæological Exploration in, J W Fewkes, 98
Flotation Method of Cleaning Coal, C. Berthelot, 511
Flour Milling, The Chemistry of, 222
Flow in Pipe Lines, The Theory of Variation of, with Surge Chambers consequent on Variation of Load on Hydraulic Turbines operated therefrom, H. H. Jeffcott, 70, The Critical Velocity of, past Objects of Aerofoil Section, E. G Richardson, 589
Flowering Plants, The Phylogenetic Classification of, J. Parkin, 340, 385
Fluid Velocity and Pressure: Prof. L. Bairstow, 152; The Measurement of, J. R. Pannell, edited by R. A. Frazer, 152
Fluorescence, The Phenomena of, determined in the Tissues by Wood's Light, A Policard, 71
Fog, London, of January 11-12, 1925, Dr. J S. Owens, 121
Food Investigation Board, Report of the, 1923, 621; required by Cattle for Maintenance and Fat Production with various Kinds of Rations, The Variations in the Quantities of, Prof J. Wilson, 787, The Preservation of, 621
Foods, Preservatives in, 217
Forest Soils The Presence of Nitrates in, A Němec and K Kvapil, 931; The Relation between the "Absolute Air Capacity" and the Degree of Acidity of, K. Kvapil and A Němec, 71
Forestry, Practical, from a Workman's Point of View, A. C Drummie, 375
Forrest, James, Lecture, The, Capt H Riall Sankey, 818
Forthcoming Books of Science, 440
Fossil: Anthropoid Ape from Taungs, The, Sir Arthur Keith, 234, Prof. G Elliot Smith, Sir Arthur Smith Woodward, 235, Dr W. L H Duckworth, 236, Bone, Mineralogy of, A F Rogers, 656, Fishes, The Oldest, Sir Arthur Smith Woodward, 124, Man in Spain, Prof H Obermaier, 151
Fossils and Leonardo da Vinci Dr P E Spielmann, 763
Fowl, Domestic, Unilateral Vasoligation in the Senile Male of the, Dr F A E Crew, 929
Frankfurt University, Prof Wieland offered the chair of pharmacology in, 248
Free Thought in the Nineteenth Century, Some Phases of the History of, Lord Oxford and Asquith, 917
Freezing of Beef for Export, The Changes which take place during the, W J. Young and J R Vickery, 555
Freiburg University, Prof K Fajans invited to the chair of chemistry in, 856
French Légion d'Honneur, Prof B Brauner awarded the cross of a chevalier of the, 132, tax in aid of French scientific laboratories, proposed, 507
Frequency Meter of Long Range, A Direct-reading, A Campbell, 178, Table, The, Dr G F Hill, 963
Freshwater Ostracods, The Segmental Excretory Organs of certain, H G. Cannon, 821
Freud Sigmund, his Personality, his Teaching, and his School, Dr F Wittels, translated by Eden and Cedar Paul, 867
Fritz, John, gold medal, award of the, to J F Stevens, 312
Frog, Three Cases of Abnormal Anterior Abdominal Veins in the, Dr. Nellie B Eales, 606
Fruit. Growing, Pollination and Commercial, C. H. Hooper, 474, Temperatures in California, 510
Fuel: Gas, The Analysis of, 991; Mixtures, Vapour Pressures of, J S Lewis, 994, Oil Resources of the Future, H B Milner, 21, Research, 109
Fuels and Fuel Testing, 850
Fulcher Hydrogen Bands, The, Dr W E. Curtis, 212

Gallus Bankiva, The Oogenesis of, Dr. F W. R. Brambell, 893
Galton. Francis, The Life, Letters, and Labours of, Prof. Karl Pearson 2 vols, 631, The Greatness of, 631
Galvanometers, Magnetism of the Coils of, G. Williamson, 99
Gambusia holbrooki (Grd.), Numerical Disproportion of the Sexes in, Analysed as to its Manifold Causes, C. Artom, 402
γ-ray Spectra, The, by the Crystal Method, J. Thibaud, 352
γ-Rays: Effective Wave-lengths of, Prof. J. A. Gray, 13; Scattering and Absorption of, Prof J. A Gray, 86
Gamma Spectra, Research on Characteristic, by Crystalline Diffraction, J. Thibaud, 286
Ganges: Navigation and Fishing on the, H. Balfour, 622; The Boats of the, and the Fishing Methods of the, J. Hornell, 622
Gas. Blue Water, The Manufacture of, Dr. A. Parker, 501; Turbines, M König, 779
Gaseous: Combustion at High Pressures. Pt. V., Prof. W. A. Bone, D M. Newitt, and D. T. A. Townend, 998; Fluid, The Influence of the Cooling of a, previous to its Compression, G Patart, 286; Mixtures: Inflammable, Effect of Infra-red Radiation upon,

the Rate of Combustion of, W T David, 999, Thermal Separation in, G. A. Elliott and Prof I Masson, 857
Gases: The Thermal Conductivity of, Prof T H Laby and Miss Nelson, 555, A New Diamagnetic Phenomenon in, Dr. A Glaser, 64, Mixed, A Method of finding the Composition of Adsorption Films of, W. G. Palmer, 402, The Kinetic Theory of, Prof E. Bloch. Translated by P A Smith, 189
Geber, The Identity of, E J. Holmyard, 208
Geine, The Extraction and Properties of, a Glucoside giving rise to Eugenol, contained in *Geum urbanum*, H. Hérissey and J Cheymol, 447
Gelatin: Jellies, The Elasticity of, and its bearing on their Physical Structure and Chemical Equilibria, H. J Poole, 894, The Physico-chemical Properties of, The Rotatory Power, F Vlés and E Vellinger, 483
Genesis: New Light on, or Creation during Descent in the Scriptures, Rev M Morris, 795
Genetics and Eugenics a Text-book for Students of Biology and a Reference Book for Animal and Plant Breeders. Third edition, 489
Geodynamische Probleme I Isostasie und die ursächliche Einheit von Gebirgsbildung und Vulkanismus Teil 2, A: Tektonik und Metamorphose, B Die Widersprüche in der Kontraktionstheorie, Dr C G S Sandberg, 791
Geographical: Association, Annual Meeting of the, 67, Congress, The International, 620
Geography: and World Development, 327, and World Power, J Fairgrieve Fifth Impression, 327, Elementary Commercial, Dr H R Mill and F Allen, 327, Human, an Attempt at a Positive Classification Principles and Examples, J Brunhes Translated by Prof I C Le Compte Edited by I. Bowman and Prof. R. E Dodge, 76, Local, C G Beasley, 652, The Teaching of, 623
Geological Society of London awards of the, 96, election of officers of the, 472, Survey in Scotland, M Macgregor appointed assistant director of the, 60
Géologie séismologique La, les tremblements de terre, Comte de Montessus de Ballore, 112
Geometry? What is, Prof G H Hardy, 139
Geotektonische Hypothesen eine kritische Zusammenstellung, Prof F Nölke, 791
German: Museum of Science and Technology, The, 611, Scientific and Medical Association, The, 313
Glasgow. Royal Technical College, Report for 1923-24, 69, anonymous gift to, 320; Journal of the, 516, University: appointment of J M F Drummond to the regius chair of botany, 68, the Hall bequest, Dr J S Haldane appointed Gifford lecturer for 1926 and 1927, 444; conferment of the D Sc on F Y Henderson, 660
Glass: as an Instrument of Human Progress, Prof W E. S Turner, 652, The Surface of, The Absorption of Water Vapour and of some other Vapours by, d'Huart, 1000; Viscosity and Allotropy of, le Chatelier, 888, Weights, Sir Flinders Petrie, 963
Glasses, The Transparency of, in the infra-red, F Liana, 554
Glycol, The, CH C CH(OH) CH_2(OH), Lespieau, 483
Gobi, Geology of the, C P. Berkey and F K Morris, 28
Goitre, Cancer and, Dr P Stocks, 437
Gold, On the Series Spectrum of, Prof. J C McLennan and A B. McLay, 998
Golgi: Apparatus L A Harvey, 777, Mitochondria and Nuclei, Dr. R J. Ludford, 922, The part played by the, in Secretion and its Subsequent Reformation in the Cells of the Oviducal Glands of the Fowl, Dr F. W. R. Brambell, 286; Bodies in the Living Cell, Observations on the, A. S Rau, Dr. F W R Brambell, and Prof. J. B. Gatenby, 249, -Cox Preparations mounted permanently in Series, Dr. C Da Fano, 786, In the Vertebrates, The Vacuome and Apparatus of, M. Avel, 663
Graphic Statistics in Management, W. H Smith, 454
Graphitic Conduction in Conjugated Chains of Carbon Atoms: a Contribution to Armstrong's Theory of Chemical Change, Prof. T M. Lowry, 376
Grassland Area, Cameroon, Tribes of the, Capt. L W. G. Malcolm, 547
Grassot Fluxmeter, A Shunted, M. Sase, 63
Gravitational Forces in Spiral Nebulæ, Prof. E Brown, 776
Gravity: Submarine Measurements of, Dr F A V. Meinesz, 550, The Determination of, at Sea in a Submarine, Dr F. A V Meinesz, 685
Great Britain Local Natural History in, 281; Sugar Industry in, 352
Greek Alchemy, E J Holmyard, 257
Greenwich and the Cape, Astronomical Observations at, 66; The Royal Observatory, Annual Visitation, 927
Gregarines, Some New, B L Bhatia and S. Setna, 437
Gregory's, Prof, Expedition to Yunnan Blattidæ collected by, R Hanitsch, 107, Orthoptera (except Blattidæ) collected by, B P Uvarow, 107
Greifswald University, Prof B Helferich invited to the chair of chemistry in, 784
Growth, and Death, Dr G P Bidder, 480, -ratios, Constant Differential, and their Significance, Dr G P Bidder, 155
Gun Wire, Dr Greaves, 279
Guthrie Lecture, The, Prof W Wien, 780
Gyro-magnetic Effect, The, J W. Fisher, 857

Haber Equilibrium, The, L J Gillespie, 549
Haddock Biology, H Thompson, 551
Hadîth Concordance in Arabic Literature, The Development of the, M H Hosain, 107
Hæmatite, Effect of Alternating Magnetism on, W M Mordey, 778
Hæmatoporphyrin, The Fluorescence of some Metallic Compounds of, C Dhéré, A Schneider, and T van der Bom, 106
Hæmocyanins, The Respiratory Functions of the, A C Redfield and A L Hurd, 823
Hæmoglobin Interchange of, in Physiological and Pathological Conditions, Dr E Greppi, 66, The Kinetics of, III, Dr H Hartridge and F. J W Roughton, 445
Hafnium Oxide in Tungsten Filaments, J A M van Liempt, 194, Zirconium and, The Atomic Weights of, Prof G Hevesy, 335, and Oxides, Prof. G Hevesy and V. Berglund, 29
Halides of the Alkali Metals at very low Temperatures, The Thermal Expansion of, Frl A Henglein, 887
Halley Lecture, The, Prof J Joly, 851
Halogen Isotopes and Infra-red Reflection Spectra, A H Pfund, 591
Hardness and Annealing Temperature, The Effect of Grain-size upon, H T Angus and P F Summers, 661
Harkness Fellowships, Establishment of, for British Graduates, 284
Harvard-Boston Expedition to Egypt, Discovery by the, 433
Health in the Tropics, 593
Hearing, The Theory of Prof E W. Scripture, 228; G Wilkinson, 379
Heat Conduction of, The Equation of the, Marion C Gray, 554, the Mechanical Equivalent of, Experiments on, Prof T H. Laby and E O Hercus, 555
Heats of Oxidation, J E Moose and S W Parr, 246, Specific, The Measurement of the Ratio of the, Using Small Volumes of Gas, J H Brinkworth, 321
Heavens, The, J H Fabre, Translated by Dr E E Fournier d'Albe, 188
Heavy Elements, the *K* Series of the, The Spectrographic Study of, G Réchou, 787, -Oil Engines (James Forrest Lecture), Capt H Riall Sankey, 818
Hebrew University in Jerusalem, The, 681, 997
Helium, and Airships, R T. Elworthy, 158; Band Spectrum of, Structure of the, III, Dr W E Curtis and R. G Long, 857; Electrons in, Double Impacts by, G Glockler, 909; E. G Dymond, 910, Chemical Combination of, Dr E H Boomer, 16, Liquid and Gaseous, The Densities of, E. Mathias, Dr C A Crommelin, Prof H K Onnes and J. C Swallow, 960, The Mobilities of the Positive Ions in, H. B Wahlin, 483, The Rectilinear Diameter of, E Mathias, Dr. C. A. Crommelin, Prof. H. Kamerlingh Onnes, and J. C. Swallow, 694

Helix pomatia, The Nutritive Value of, L. Léger, 250
Hellenistic Philosophies, P E. More (The Greek Tradition from the Death of Socrates to the Council of Chalcedon, 399 B C. to A.D. 451, Vol 2), 189
Helmholtz's Physiological Optics, The Translation of, Alice Everett, 424
Herring: The, B Storrow, 755; Investigations, B. Storrow, 547, The, in Relation to its Animate Environment, Part I, A C Hardy, 755; Young, in the southern North Sea and English Channel, First Report on, Part I., Dr W Wallace, with Appendix, J N. Carruthers, 755
Herrings of the North Sea, On the Summer—and Autumn—Spawning, Dr A C Johansen, 755
Hertzian Waves The Perturbations of the, during Transmission to Great Distances, G Bigourdan, 446; The Propagation of, to Great Distances, G Bigourdan, 358
Hexylresorcinol, a New Urinary Antiseptic, Dr Leonard, 275
High Altitudes, A Hot Wire Apparatus for Measuring, E Huguenard, A Mangan, and A Planiol, 816; Grass Trail The, being the Difficulties and Diversions of Two, Trekking and Shooting for Sustenance in Dense Bush across British Central Africa, F Savile, 332, Tension Electric Fields, Effect of, upon the Discharge of Locomotive Gases, Dr P L Mercanton, 874
Hill Pasture and Sheep Grazing, The Relation between, W G Smith, 661
Himalayas Flight over the, A Cobham, 205; In the High, Sport and Travel in the Rhotang and Baralacha, with some Notes on the Natural History of that Area, H Whistler, 492
Hindu Astronomy, G R Kaye, 770
d'Histologie Appliquée, Bulletin, 313
Historic Scientific Instruments in the Old Ashmolean Museum, Oxford, 783
Historical Atlas of the British Empire, 528
Hittite Problems, Prof Hrozny, 773
Hoddesdon, The Conference at, on Special Libraries and Information Bureaux, 615
Hohenheim Agricultural Hochschule, Dr. P Brigl nominated professor and director of the Institute of Agricultural Chemistry at, 248
Holmium, F H Duggs and B S. Hopkins, 549
Homoptera, Male Genitalia of, The Development of the, Dr Hem Singh-Pruthi, 475
Hookworm Larvæ, Observations on, Dr L F Hirst, 350
Hop, Virus Diseases of the, Prof. E. S Salmon and W M Ware, 993
Hops, The Preservative Properties of, A Chaston Chapman, 244
l'Horlogerie, L'Evolution de, Reverchon, 24
Hormones, Sexuality and, 7
Horn, Around the, to the Sandwich Islands and California, 1845–1850 Being a Personal Record kept by Prof. Chester S. Lyman Edited by Prof. F J Teggart, 418
Hos of Kolhan: Physical Characteristics of the, D. Majumder, 823, The Terminology of Relationship of the, D Majumder, 931
Hull, Gift by T. R Ferens towards a University College for, 239
Human Biology, Studies in, Prof R Pearl, 671; Geography an Attempt at a Positive Classification—Principles and Examples, J. Brunhas. Translated by Prof I C. Le Compte. Edited by I Bowman and Prof R E Dodge, 76
Humanism and Technology and other Essays, Principal C. Grant Robertson, Sir Thomas H Holland, Prof. C. H Desch, Sir Henry Fowler, Prof F. W. Burstall, Prof W. Cramp, 527
Hunan, the Chinese Province of, Map of a Journey in, Dr. H. Handel-Mazzetti, 520
Huxley: Sir E. Ray Lankester, 702, Thomas Henry, Prof. E. B Poulton, 704, Centenary, The. 649, 697; A Student's Reminiscences, Rev E F. Russell, 751; and Evolution, Dr. W. Bateson, 715, as Anthropologist, Sir Arthur Keith, 719; as Evolutionist, Prof. J. A. Thomson, 717; as Teacher, Prof. Patrick Geddes, 740; Biological Science, Teaching of, Prof. F. O. Bower, 722; Contributions: to our Knowledge of the Invertebrata, Prof. E. W. MacBride, 734, to the Study of the Invertebrata, Prof E. W. MacBride, 838; to Vertebrate Palæontology, 728; Enduring Recollections, Prof H. F. Osborn, 726, Evolution and Man, E Clodd, 724; Geological Thought and Teaching, Prof W W Watts, 732; Home Memories, Dr. L. Huxley, 698; Medal of the Royal Anthropological Institute, The, awarded to Sir William Ridgeway, 392; Memorial Lecture and Medal of the Royal Anthropological Institute, 752, Personal Impressions, Prof C. V Boys, 751, Plant Biology in the 'Seventies, Sir W T. Thiselton-Dyer, 709, Processes of Life and Mind, Prof C. Lloyd Morgan, 737, Structure and Evolution in Vertebrate Palæontology, Prof D. M. S. Watson, 730; The Master, Prof W. J Sollas, 747; Truth and Righteousness, S Paget, 748
Huxley's Message in Education, Prof H E Armstrong, 743, to the Modern World, Prof. T D A Cockerell, 750
Hydra and the Tadpoles, Prof S. J Hickson, 802, Chimæras, V Issayev, 438
Hydrazine, Action of, on the Halogen Derivatives of Malmamides and of Acetoacetic Esters, E L Hirst, A K Macbeth, and D Traill, 894
Hydrellia Griseola, The Occurrence in Britain of, P H. Grimshaw, 661
Hydrochloric Acid, Activity Numbers of, H S Harned and M E Flevsher, 280
Hydrodynamics and Electrical Analogies, Prof V Bjerknes, 246
Hydrogen. Active, The Condensation and Re-evaporation of, F Paneth, 171, and Oxygen, The Union of, in Presence of Silver and Gold, D L Chapman, J E Ramsbottom, and C G Trotman, 177, and Palladium, An Investigation of the Relationships existing between, B Lambert and S F Gates, 786; at Higher Pressures, The Secondary Spectrum of, I Sandeman, 858, Atoms for α-particles, A Theoretical Study of the Stopping Power of, R H Fowler, 966, into Air, The Diffusion of, measured by the Interferometer U-gauge, Dr C Barus, 179; -ion Concentration and the Oxidation Reduction Potential of the Cell Interior, J. and Dorothy Needham, 893; many-lined Spectrum of, Wave-lengths of Additional Lines in the, T Tanaka, 517, Nuclei and Atoms, Collision between, E Fermi, 627, Peroxide. The Action of, on the Magnesium Arylamines, J F Durand and R. Naves, 519, The Decomposition of, in the Presence of Nickelous Hydroxide, Mlle D Veil, 663, Secondary Spectrum of, Regularities in the, Prof O W Richardson and T Tanaka, 517, Spectrum, Secondary, Structure in the, Prof O W. Richardson, 858, Sulphuretted, The Separation of Zinc and Nickel by, H. Kling and Mme. A Lassieur, 519, The Mechanism of the Production of, at the Expense of Glucose by the Coli Bacillus, E. Aubel and J Salabartan, 823
Hydrography, Sound and Wireless in, Comdr. N H. Heck, E A Eckhardt, and M Keiser, 584
Hydrology Medical, Outlines for Practitioners and Students, Dr R F Fox, 375
Hydrolysis, The Isolation of a Product of, of the Proteins hitherto undescribed, S. B. Schryver, H. W Buston, and D H Mukherjee, 445
Hydroxylamine, Isolation of, C de W. Hurd and H. J. Brounstein, 246
Hymenomycetes, some, growing on Wood, The Specificity of, L. Lutz, 626
Hypothecate, "One who has done so," 912

Ice: Crystallisation, The Velocity of, through Supercooled Gelatin Gels, E H Callow, 858; in the Arctic Seas in 1924, 617, in the Baltic Sea, 351; Physical Constants of, O. Maass and L. J. Waldbauer, 279; The Specific Inductive Capacity of, B. de Lenaizan and J. Granier, 322
Igneous Rocks, Classification of, E. T. Hodge, 519
Iguanodon Tracks in the Neocomian of the Island of Brioni near Pola, The Discovery of, A. Bachofen-Echt, 627
Illuminating Engineer, January, 277
Illumination, Industrial, P. W. Cobb and F. K. Moss, 868,

Imperial: College of Tropical Agriculture, The, 183 of Science and Technology, The, and the University of London, 997, Institute, Bulletin of the, 579, Research, a Committee of, 845, 861
Incubation: Artificial, L. B. Atkinson, 282, C. J. P. Cave and T. V. Jones, 498, The Physics of, Prof. A. P. Chattock, 141
Index Kewensis, the, 205
India. Chemistry in, 175, Dr. M. O. Forster, Prof. J. F. Thorpe, 281, Heavy Rain in, Frequency of, Sir Gilbert T. Walker, 29, North-west, Probable Weather in, Jan., Feb., and March, J. H. Field, 275, Possible Effect of the Salt-tax in, Dr. F. M. Gibson, 987, Southern, Primitive Mural Decoration in, the late Dr. N. Annandale, 206, Survey of, Auxiliary Tables of the, fifth edition, revised and extended by Dr. J. de Graaff Hunter, 3 pts., 223, The Administration and Control of Religious Trusts in, 810
Indian Antiquary, the, transferred to the Royal Anthropological Institute, 132, Archæology, R. Chanda, 474; Diplopterous Wasps, Further Notes on the, C. Dover, 142, Earthworms, Some, Dr. J. Stephenson, 394, Kala Azar Commission, Lt.-Col. S. R. Christophers, 420, Molluscs, Growth in, Major R. B. S. Sewell, 350, Origins, H. B. Hannah, 823, Plant Breeders' Conference at Surat, 849, Science Congress, programme of the, Benares, 25, Universities Conference at Simla, Report of the, 33, The Development of, Sir Henry Sharp, 693
Indo-Australian Archipelago, The Amphibia of the, Prof. P. N. van Kampen, 12, China, Archæological Exploration in, Dr. R. Verneau, 886
Indole, A New Research Institute at, for the Improvement of Crops, 59
Industrial Chemist and Chemical Manufacturer, The, 348, Fatigue, Dr. C. S. Myers, 851, Institute, the aims of the, 811, Psychology, National Institute of, Report of the, 472
Infra-red Spectrum of the Alcohol Function, The, J. Lecomte, 626
Infusoria, The Action of External Factors on the, E. Chatton and Mme. Chatton, 787
Inks, Typographic, Dr. N. F. Budgeon, 352
Insanity, Crime and, Dr. W. C. Sullivan, 414
Insect, The Great Little, Evelyn Cheesman, 414
Insectes parasites de l'homme et des animaux domestiques, Les, E. Ségny, 189
Insects, Everyday Doings of, Evelyn Cheesman, 414, Genital Ducts of, Homologies of the, Hem Singh Pruthi, 763
Insulation, Recent Improvements of, K. G. Maxwell and A. Monkhouse, 810
Insulin: Inorganic Phosphates and Hypoglycæmia produced by, A. Desgrez, H. Bierry, and F. Rathery, 999, The Action of, on the Nitrogen Metabolism, H. Labbé and B. Théodoresco, 931
Interferometer, A Simple, L. Richardson, 582
Inter-library Loans, Regulations for, 505
Intermetallic Compounds, Preparation of, by the Wet Method, A. Mazzucchelli and A. Vercillo, 695, Reactions in a Lead-base Bearing Metal, Prof. O. W. Ellis, 382
Internal Secretions, The, for the Use of Students and Physicians, Prof. A. Weil, translated by Dr. J. Gutman, 907
International: Critical Tables, The, 32, Relations, The Universities and, 521, 557
Intersexuality in Fowls and Pigs, Dr. F. A. E. Crew, 661
Inter-State Post-graduate Assembly, Visit of the, to London, 917; to Edinburgh, 988
"Intertraction Phenomenon" between Solutions and the Molecular Significance of Negative Surface Tension, An Explanation of the So-called, N. K. Adam and G. Jessop, 553
Iodine in *L. flexicaulis*, The Conditions of the Stabilisation of, P. Freundler, 142
Iodocadmium Complex, The Spectrographic Study of the, P. Job, 787
Iodo-succinimide: An X-ray Examination of, Kathleen Yardley, 786; The Crystallographic and Optical Properties of, Dr. A. E. H. Tutton, 786
Ion, The Various Magnetic States of an, G. Foex, 662
Ionic Mobility, Measurement of, D. A. MacInnes and coworkers, 924
Ionisation: Equilibrium, Influence of Radiation on, Prof. M. Saha and Romani Kanta Swe, 377; Dr. J. Woltjer, Jr., 534, in the Atmosphere, The Equilibrium of, J. J. Nolan, R. K. Boylan, and G. P. de Laehy, 589; Potential, The Thermodynamical Interpretation of, N. Perrakis, 70, Potentials, Critical, Prof. K. T. Compton and Dr. F. L. Mohler, 443
Ions, Complex, Detecting, W. H. Patterson and F. Duckett, 816
Ipsilateral Contraction and "Inhibitory" Rhythm, E. G. T. Liddell and J. F. Fulton, 821
Ipswich, The Archæology of, from Pliocene to Anglo-Saxon Times, J. Reid Moir, 614
Ireland, Geology of, Handbook of the, Dr. G. A. J. Cole and T. Hallissy, 832
Irish Butter, certain Empirical Standards in their Application to, The Interpretation of, G. Brownlee, 402, Radium Committee, Report of the, 1924, 967, Sea Herring, A. Scott and others, 654
Iron and Chromium, the Sesquioxides of, The Magnetic Study of the Stable Form of, L. Blanc and G. Chaudron, 359, and other Metals, Passivity of, Dr. A. S. Russell, 455, and Steel, Defining, Prof. Honda, 656, Specific and Latent Heats of, A. Mallock, 14, Crystals, The Magnetic Properties of, W. L. Webster, 213, in the Schumann Region, The Spark Spectrum of, L. and E. Bloch, 141, Magnetic Sesquioxide of, H. Abraham and R. Planiol, 930, Pharmacological Investigations on, VI., L. Sabbatani, 143, The Plastic Deformation of, and the Formation of Neumann lines, Dr. W. Rosenhain and Miss J. McMinn, 786, The Polymorphic Forms of, F. Wever, 208
Islands: West Indian—Ægean, Sir Arthur E. Shipley, 797
Isopyknomeric Analysis, Fusion Mixture for, E. Clarici, 895
Isostasie und Schweremessung: ihre Bedeutung fur geologische Vorgange, Prof. A. Born, 487
Isostasy, Dr. J. W. Evans, 487, and Geology, A. C. Lawson, 618
Isotopes: Dr. F. W. Aston, second edition, 222, les éléments, L'Isotopie et, Mme. P. Curie, 453, The Separation of, by the Ionic Migration Method, J. Kendall and J. F. White, 179
Italian Theses on Chemistry and Physiology, 66

Jamaica, An Impression of, and the Panama Canal Zone, Sir James K. Fowler, 594
Japan: A Severe Earthquake in, 847; Central, Carboniferous Rocks in, I. Haysaka, 278, The Metric System in, 132
Japanese Earthquake of 1923, The, Dr. C. Davison, 171, K. Suda, 65, K. Shiraton, 655, *Journal of Mathematics*, Part 1, 776
Jefferson Physical Laboratory, Contributions from the, and from the Cruft High-Tension Electrical Laboratory of Harvard University for the years 1922 and 1923, Vol. 16, 225
Jelly-fish, Vitality of, de Beer and Huxley, 62
Jena University, Dr. W. Hieber appointed director of the department of inorganic chemistry, 320
Jerusalem, Hebrew University in, The, 681; gift to, by B. Baron, 997
Jet-wave Accelerometer, The, Dr. J. Hartmann, 872
Joule Effect, Recent Measurements of the, for CO_2, F. G. Keyes and F. W. Sears, 591
Julian Day, The Beginning of the, 473
Jurassic Echinoderms of Sinai, R. Fourtau, 815, Insects, A New Locality for, Prof. T. D. A. Cockerell, 947

K Absorption Levels of the Light Atoms, The: A Correction, Dr. H. Robinson, 945
Kaiser Wilhelm Institute, The, Dr. H. Freundlich, 94
Kala Azar: Commission, Indian, Lt.-Col. S. R. Christophers, 420; Use of Stibamine in, Dr. Napier, 509
Kalendar for 1923, Sir Napier Shaw, 61
Karakorum Mountains, Scientific Exploration in the, 371

Kashmir, Ancient, A Mystic Poetess of, S. M. Edwardes, 526
Kelvin Lecture of the Institution of Electrical Engineers, The, Dr J H Jeans, 240, 346, 361
Kenya: The Vanishing Tribes of: a Description of the Manners and Customs of the Primitive and Interesting Tribes dwelling on the Vast Southern Slopes of Mount Kenya, and their Fast Disappearing Native Methods of Life, Major G St J Orde Browne, 866
Kew, Royal Botanic Gardens: Display of Plants of Botanical and Educational Interest, 883, Handlists of, 990, Postcards of the, 920, Work and Influence of the, 897
Kidney, The Isolated, The Action of Inorganic Salts on the Secretion of, F Eicholtz and Prof E H Starling, 357
Kilauea, Tidal Oscillations in the Lava Pit of, E. W Brown, 688
Kimilaroi and White: a Study of Racial Mixture in N S W, Prof G Taylor and F Jardine, 555
King Edward's Hospital Fund, Science Lectures on behalf of, 26
King's Birthday Honours List, The, 917
King's College for Women, Household and Social Science Department, Miss Helene Reynard appointed Warden, 997
Kirstenbosch, National Botanic Garden at, The, 990
Knowledge, Prolegomena to an Idealist Theory of, Prof N Kemp Smith, 903
Kodaikanal Observatory in 1924, The, 921

La Courtine, The Propagation of Aerial Waves as shown by the Experiments at, C Maurain, 106
Lake Dwellings in Europe, The, in the Light of the New Excavations, V Gordon-Childe, 965
Lallâ the Prophetess, The Word of: being the Sayings of Lal Ded or Lal Diddi of Kashmir (Granny Lal), known also as Lalêshwarî, Lallâ Yôgîshwârî and Lâlishrî, between 1300 and 1400 A D: Done into English Verse from the Lallâ-vâkyâni or Lal-Wakhi, and annotated by Sir Richard Carnac Temple, 526
Lamprey, A Problematical Organ in the, G. R de Beer, 27
Land: Economics, Elements of, Dr R T Ely and E. W Morehouse, 220; Planarium, A New British, E. Percival, 992
Langley, Dr. S P, Biographical Byways, Dr C G Abbot, 455
Lanthanum Thallous Sulphates, F Zambonini and G Carobbi, 895
Lapse Rate, The Measurement of the, by an Optical Method, N K. Johnson and O F T Roberts, 482
Latin as the Language for Science, Prof R G. Kent, 23
Latitude Variation of, H Kimura, 26, Variations of, averaging by Tenths of a Year in, J Boccardi, 70
Lattice Points of a Circle, The, Prof G H. Hardy, 400
Laue Diagrams, The Production of, by Means of Monochromatic X-rays, and the Structure of Mother-of-Pearl, J H Shaxby, 250
Laughter, The Nature of, J C Gregory, 903
Lawes Agricultural Trust Committee, Lord Clinton appointed chairman of the, 775
Lead: Accumulator A, incapable of being Sulphated, C Féry, 35, 64, Isotopes, Band Spectra of, Dr E S Bieler, 980, the Isotopes of, Chemical Studies on, H Brennan, 359, The Isotopy of, Mlle Berthe Perrette, 1000, Tubing, Animal Attacks on, G Loder, Prof R Hesse, 548
League of Nations Committee on Intellectual Co-operation Index Bibliographicus. International Catalogue of Sources of Current Bibliographical Information (Periodicals and Institutions) Arranged and edited by M Godet, 636, The Activities of the, 95
Leeches from Kashmir, Dr J P. Moore, 510
Leeds: Co-operative Field Naturalists' Club, T. Sheppard elected an honorary life member of the, 849; University: Annual Report for 1923–24, 69; resignation of Prof T W. Griffith, 320, award of doctorates to H. Hunter and C. G K Sharp, 398, J. Gordon appointed lecturer in bacteriology; Mrs H W Swift appointed an honorary demonstrator in the department of zoology, 515; appointment of Dr. W. H M Telling to the chair of medicine, 964; Prof. J. W. Cobb elected Pro-Vice-Chancellor, 997
Lehmann's so-called Liquid Crystals, Prof. G. Friedel, 274
Leicester, University College, bequest to, by H. S. Gee, 284
Leidy, Joseph, Memorial award, to be made to Prof. H. S. Jennings, 812
Leidy's Acanthocephala, Critical Study of, Dr. H J. van Cleave, 510
Lemon Culture, Emulsified Oil-sprays for, W. W Yothers and J. R Winston, 655
Leonardo da Vinci, Fossils and, Dr P E. Spielmann, 763
Leonardo, No 1, 393
Lepidium sativum watered with Salt Water, Extension of Acquired Character and Facts of Heredity in, P. Lesage, 627
Lepidosiren paradoxa, Studies on, Miss Frances M. Ballantyne, 929
Libyan Desert, Ancient Rock-sculptures in the, D. Newbold, 315
Life and Science, Prof D Fraser Harris, 259, and Word, an essay in Psychology, Dr. R E Lloyd, 760, Phenomena, Chemical Dynamics of, Prof O. Meyerhof, 905, The Nature of, Prof. W J. V Osterhout, 906, without the Pancreas, E. Hédon, 519
Light and Sound: a Text-book for Colleges and Technical Schools, Profs W S Franklin and B MacNutt, 11; from the Stars, The Velocity of, M Salet, 813; reflected by Insects, The Circular Polarisation of the, P Gaubert, 35, Relation of, to Bird Migration and Developmental Changes, W Rowan, 494, Stimuli in Plants, Modern Conceptions of, Prof F A. F. C Went, 883; The Biological Action of, D T Harris, 445; Prof L Hill, 642, The Nature of, and its Measurement, J W T Walsh, 614, The Structure of (Fison Memorial Lecture), Sir J J Thomson, 774, the Velocity of, The Effect of the Earth's Rotation on, Sir Joseph Larmor, Dr J H Jeans, 638; Profs A A Michelson and H G Gale, 566
Lighting in Relation to Public Health, Prof Janet Howell Clark, 601; of Buildings, The Natural and Artificial, P J Waldram, 614, Progress in, 25
Lightning, C J P Cave, 801, The Sound of, Dr W L. Balls, 912
Ligia novæ-zealandiæ in South America, Prof. C Chilton, 475
Limbs and Pigment-Cells, Prof J Graham Kerr, 154
Lime, The Association of, with other Oxides of RO-type in Minerals, A Brammall, 858
Limonene, The Electrical Double Refraction of, R de Mallemann, 967
Linear Integral Equations, Prof W V. Lovitt, 492
Linnean Society: election of officers, 956; Dr. N L. Britton, Prof G. H Parker, Prof. F Raffaele, Prof. C Schröter, and A Zahlbruckner elected foreign members of the, 849, gold medal, the, presented to Prof F W Oliver, 956
Liquid-gas Interface, The Electrical Conditions arising at a, H W. Gilbert and P E. Shaw, 822
Lister Memorial Lecture, the first, Sir W Watson Cheyne, 810
Lithium Solutions in Liquid Ammonia, C. A. Kraus and W C Johnson, 994
Liverpool: Marine Biology Committee. L.M.B C. Memoirs on Typical British Marine Plants and Animals 26: Botryllus, E Catherine Herdman, 492; University, honorary degrees conferred on Sir J. C. Irvine and Sir Dugald Clerk, 997
Living Things, The Study of. Prolegomena to a Functional Biology, Dr E S. Russell, 218
Livingstone College, Annual Report of the, 132
Llandovery. and Associated Rocks of Garth (Breconshire), The, G Andrew, 624; District (Carmarthenshire), The Geology of the, O T. Jones, 624; Rocks, The Relations between the, of Llandovery and those of Garth, G Andrew, 624
Locomotion, Stevenson's, 955
Locust Problem and its International Solution, The, P. Vayssière, Dr A. D. Imms, 31
Logarithmetica Britannica: being a Standard Table of Logarithms to Twenty Decimal Places, A. J. Thompson, Part 9, 111
Logarithms de Luxe, 111

London: Fog of January 11-12, 1925, Dr J S Owens, 121, School of Tropical Hygiene and Tropical Medicine, appointment by the, of Dr G R Ross as a Rhodesian research fellow, 346, University conferment of doctorates, 33, 68, acceptance of a bequest by A Jubber; the income of the Laura Soames Trust Fund, conferment of the degree of D Sc, 211, Departmental Committee on, E Hilton Young appointed chairman of the, 312; J H Dible appointed professor of pathology at the London School of Medicine for Women, the title of reader in economics conferred upon Dr H Dalton, that of emeritus professor of hygiene upon Prof H R. Kenwood, and that of emeritus professor of medicine upon Sir John Rose Bradford, conferment of doctorates, Prof E Barclay-Smith and Prof O W Richardson appointed fellows of King's College, 355; award of Keddey Fletcher-Warr studentships to D C Harrison and Dr N A V Piercy, 479, chairs at Bedford College to be entitled the "Hildred Carlile" chairs; award of doctorates, 515, Report of the principal officer for 1924-25, 820, appointments in, the title of emeritus professor conferred on Prof R T Hewlett and Sir Halford Mackinder, conferment of doctorates, 856
London's: Atmosphere, Dr J S Owens, 688, Sunshine in Winter, The Effect of Pressure Distribution upon, Miss L D Sawyer, 481
Looking into Things, 523
Loranthus and Eucalyptus, The Symbiosis of, Miss Kerr, 555
Love in Children and its Aberrations a book for Parents and Teachers, O Pfister Translated by Eden and Cedar Paul, 525
Low Voltage Electric Arc, The Abnormally, Dr R Bär, 549
Lubrication, Boundary, Plane Surfaces and the Limitations of Amontons' Law (Bakerian Lecture), Sir William Hardy and Ida Bircumshaw, 480
Lumbricus, The Oogenesis of, Prof J B Gatenby, 979
Luminous Paints, 779
Lunar: Diurnal Magnetic Variation at Greenwich and other Observatories, The, Prof S Chapman, 517, Eclipse of last August, The, J Dufay and A Conder, 277, Map, New, H P Wilkins, 921, Seas, Visual Brightness of, G A Conti and G. Armellini, 627
Lyngbya nigra Ag, Variation in the Hormogones of, W B Crow, 553

Machschen Philosophie Die Grundgedanken der, mit Erstveroffentlichungen aus seinen wissenschaftlichen Tagebüchern, Prof H Dingler, 225
Madagascar, The Permian Formations of, The Existence of a Reptile with Lacertilian Affinities in, J Piveteau, 286
Magic and Medicine, C Whitehead, 170
Magnetic: Bridge for testing Straight Specimens, and an Analysis of the Hysteresis Loop of Cobalt-chrome Steel, E. Hughes, 966, Field, Directional Quantification in a, Prof W Gerlach, 316, Influence of, on Blood-vessels, P. P Lazarev, 687, The Heating Effect of a, Demonstration of, H. Perlitz, 382, Measurements in the Centre of France, L. Eblé, 787; Survey Work in the United States, 171
Magnets, Permanent, S. Evershed, 514
Maize in South Africa, E. Parish, 886
Makedonien, Ethnographie von, Prof. G. Weigand, 528
Malacon, The Treatment of, Mlle. M Marquis, P and G Urbain, 930
Malaria: Historical Aspects of, Dr. A Balfour, 17, Reflections on, Dr. A Balfour, 625, and Sleeping Sickness, The Problems of, Prof. E Brumpt, 955
Malic Acid and the Malates, The Action of Boric Acid on the Rotatory Power of, E. Darmois, 662
Malonyl Urea, The Localisation in the Organism of the Alkyl Derivatives of, P Fredet and R. Fabre, 483
Malthus and his Work, Dr. J. Bonar. Second edition, 406
Malvern Inlier, The Pre-Cambrian Volcanic Rocks of the, J. I. Platt, 694
Manchester: Literary and Physical Society, Rev. A. L. Cortie elected president of the, 811, University appointments in, 997; continuation of grant by Brunner, Mond and Co., Ltd., for physics and chemistry, regulations for the award of the Philip Buckle Research Scholarship, J. C Oakden appointed assistant lecturer in mechanical engineering, 284, Dr F. C. Moore appointed professor of systematic medicine, 399, gift from the G E.C of the U S.A, B A McSwiney appointed tutor and secretary to the Faculty of Medicine, B Thomsett appointed assistant lecturer in electrical engineering; H E Martin appointed Whitworth meteorological observer, 211, resignations of H Lowery and F. Neave, 211
Manchuria, North, and the Chinese Eastern Railway, 833
Manganese Steel, On the Hardness of, Prof C Benedicks, 230
Mangroves, The Tanning Qualities of, J. A Pilgrim, 206
Man's Evolution, The Rate of, Sir Arthur Keith, 390
Maori, Printed, A Bibliography of, to 1900, Dr H W. Williams, 296
Marconi International Marine Communication Coy., The Twenty-fifth Anniversary of the, 685
Margidunum, Excavations at, Dr F Oswald, 992
Marine: Biology at Plymouth, W de Morgan and others, 687, *Observer*, December, 24, January, 242
Mars, Observations of, F Baldet, 34
Masaryk University, Mathematics at the, 544
Mathematical Association, Annual Meeting of the, 139, Laboratory The, its Scope and Function, Prof H Levy, 139, Physics The Place of Partial Differential Equations in, being a Course of Readership lectures delivered at Patna University in 1921, Prof G Prasad, 492
Mathematics Egyptian, Prof D'Arcy W Thompson, 899, 935, University, The Reform of, Dr H B Heywood, 139
Mathématiques et de physique, Mélanges de, E Picard, 637
Medical Education, Methods and Problems of, Prof. Rosenau, 623, Research Council, Report of the, for the year 1923-1924, 325, in Great Britain, 325; Uses of Radium, 174
Medicine, Essays on the History of, presented to Karl Sudhoff on the occasion of his seventieth birthday, November 26, 1923, by Sir T Clifford Allbutt and others, 372, Magic and, C Whitehead, 170, Studies in the History of, 372
Medieval Science, E J Holmyard, 599, Weapon damascened with Tin, A, G A Le Roy, 895
Medullary Radiotherapy, Experiments in, H Bordier, 519
Medusæ of the Mediterranean and Adjacent Seas, The, Dr P L Kramp, 395
Meldola Medal of the Institute of Chemistry, award of the, to Dr L J Harris, 312
Membrane, The Vibrations of a Stretched, with a Particular Law of Density, E L Ince, 214
Mendel Gregor Johann, Leben, Werk und Wirkung, Dr H Iltis, 827
Mendeliana, Dr W Bateson, 827
Mental Defectives, The Elimination of, Major L Darwin, 838, Imagery, Modern Investigations of, Prof T. H. Pear, 853
Mercury Arc, Luminous Vapour from the, and the Progressive Changes in its Spectrum, Lord Rayleigh, 998, Helide, J J Manley, 337; A Correction, J J Manley, 947, Line 2536, The Structure of the, Prof R W. Wood, 461, Lines, The Origin of the Satellites of, Profs E P Metcalfe and B Venkatesachar, 15, Oxychlorides, The Direct Formation of the, H Pélabon, 286; Vapour: Effect of an Alternating Magnetic Field on the Polarisation of the Resonance Radiation of, Prof E Fermi and F Rasetti, 764, Engine, The, Dr. W. L. R Emmet, 396, in Vacuum Systems, A Substitute for a Liquid Air Trap for, Prof A Ll Hughes and F. E Poindexter, 979, The Isotopes of, Dr. F Stumpf, 172
Meristem Growth in Wounded Potatoes, G. A. C. Herklots, 170
Mesothorium 2, The Magnetic Spectrum of the High Velocity β-rays of, D Yovanovitch and J d'Espine, 35
Metabolism, Carbohydrate, Herring, Irvine and Macleod, and others, 137
Metaformaldehyde, Photosynthetic Theory of the Origin of Life and Production of Organic Forms with, A. Herrera, 519

Metallic Oxides, The Reduction of the, by the Alkaline Cyanides, L Hackspill and R. Grandadam, 663
Metallography, Microscopical, Practical, Dr R H Greaves and H. Wrighton, 416
Metallurgy . and its Influence on Modern Progress, Sir Robert Hadfield, 203 , Modern, Prof H C. H. Carpenter, 793
Metal Resources and the Constitution of the Earth, 914
Metals Cold-working of, and Hardness, Masing, 396 , during Cutting, Flow and Rupture of, Dr W Rosenhain and A C Sturney, 317 , Institute of, The May Lecture of the, Prof H A. Lorentz, 684 , of the Aluminium Sub-group, K. R Rao, 966 , of the Cerium Group, Double Nitrates of, with Copper and with Cadmium, G Carobbi, 402 , Plastic Extension of, The Heat developed during, W S Farren and Prof G. I Taylor, 177 , Pure, The Thermal and Electrical Conductivities of some, F H Schofield, 213 , The Abrasion of, Some Experiments on, K Honda and R Yamada, 662 , The Corrosion of, U R Evans, 793 , The Science of, Z Jeffries and R S Archer, 793
Meteor Crater, Arizona, L F S Holland, 475
Meteorite of Roda, The, A Lacroix, 286
Meteorological Discontinuities and the Atmospheres in the Neighbourhood of Mountain Chains, The Relations between Various, J. Laugeon, 554 , Office Air Ministry, Annual Report of the, 471 , The Future of the . C J. P Cave, 378 , Dr G. C Simpson, 226 , Reports by Wireless Telegraphy, 884 , Research, Swedish, 816 , Society, C. J. P. Cave elected president of the, 275
Meteorology Agricultural, appointment of a committee on, 204 , The Present Position of, and Meteorological Knowledge, C J P Cave, 167
Meteors, April, The Shower of, W F Denning, 686
Methane · A Critical Potential of, and its Absorption in the Ultra-violet, G Glocker, 591 , The Presence of, in Various Outflows of Gas observed in the Limogne d'Auvergne, 590
Methyl Alcohol Pure, H Hartley and H R Raikes, 852 , Synthetic, 622 , The Electrolysis of the Alkaline Acetates in Solution in, J Salauze, 590 , The Synthesis of, by Reduction of Carbon Monoxide, G Patart, 106
Methylalkyl-glycerols, The, R. Delaby and G Morel, 931
Methylketole Yellow, B Oddo, 695
Metric System, The, in Japan, 132
Metropolitan Museum of Art, New York, gift to the, by J D Rockefeller, junr , 60
Micellæ, Crystalline, in the Plant Cell Wall, 815
Michelson-Morley Experiment: Reported New, Prof Michelson and Dr L Silberstein , Sir Oliver Lodge, 433 ; The, Dr A Daniell, 378 , Sir Oliver Lodge, 379
Micro- analysis, Organic, Quantitative, Prof. F. Pregl Translated by Dr. E Fyleman, 188 ; dissection, Prof R Chambers, 811 , Lepidoptera, the Distribution of, Wegener's Hypothesis and, E. Meyrick, 834 ; photometer A Simple, Dr. L. C Martin, 213 , with a Photo-electric Cell, A Self-recording, P. Lambert and D Chalonge, 663
Microscope Lamps, etc , Catalogue of, Ogilvy and Co., 280 , The Hahn Goerz Workshop, F Van Neck, 893 ; The, in Metallurgy, Sir Robert Hadfield, 684 , The, in Science and Industry, A Chaston Chapman, and others, 691
Microscopes Petrological, Swift's Catalogue of, 472 ; The Crisp Collection of, Dr. R T. Gunther, 265
Microseismic Disturbances at Dakar (Senegal), H Hubert, 106
Middle and Upper Eocene Floras of South-eastern North America, Dr. E. W. Berry, 819
Milk : Products, Faults in, The Separation and Identification of the Micro-organisms causing, Miss E R Hiscox, 446 ; The Enumeration and Differentiation of the Various Cellular Elements of, by means of the Microscope, A T. R. Mattick, 446
Miller's Recent Experiments, and the Relativity Theory, Dr. L. Silberstein, 798
Mimosa : *pudica*, The Conduction of Excitation in the Leaf of, K. Umrath, 403 ; *spegazzinii*, Conduction of Excitation in the Leaf of, R Snow, 553
Mind and Brain, Prof J S Bolton, 848
Mineralien, Mikroskopische Physiographie der petrographisch-wichtigen, H Rosenbusch. Band I. Erste Hälfte Fünfte Auflage, Prof E A Wülfing. Zweite Lief , 148
Mineralogical and Crystallographical Nomenclature, International Agreement in, Dr L J Spencer, 214
Minerals, The Recognition of, by their Optical Characters, 148
Mining and Metallurgy, Institution of · Sir Thomas H. Holland elected president of the, 652 , awards of the, 616 , Research Laboratory of the University of Birmingham, Report of the, 477
Minnow, The Changing Colour of the, L Abolin, 62

Petrols, The Ultra-violet Absorption of, F. Vlès and Mlle. M Gex, 286
Petromyzon fluviatilis, Dimensions reached by, and the Phenomenon of Contraction, G Cotronei, 143
Pflanzenanatomie, Handbuch der, Herausgegeben von Prof K Linsbauer Allg Teil Cytologie Band I. Die Plastiden, Dr P N Schürhoff, 930, Allg Teil: Cytologie Band III/2 Die Zellmembran Prof C. van Wisselingh, 976
Phacelia tanacetifolia, Influence of Light on the Germination of, M Nicolic, 214
Phantoms, The Passing of the a Study of Evolutionary Psychology and Morals, Prof C J Patten, 218
Pharmacists' Botany, The, Dr G B Rigg, 296
Phenological Research, International Co-operation in, J E Clark, 602
Phenyl-*p*-nitrocinnamic acid, Ethyl ester of, F Ranfaldi, 519
Philippine Earthquakes, Catalogue of, Rev M S Masò, 395
Phillips, John, Dr W E Collinge, 885
Philosopher, The Travel Diary of a, Count H Keyserling. Translated by J H Reece, 977
Philosophical Studies, the Institute of, 991
Philosophy and Science, 450, The Scientific Approach to, Selected Essays and Reviews, Prof H Wildon Carr, 450
Phœnix dactylifera from Cyrenaica, Floral Atrophy in, F Cavara, 627
Phosphorus. Chloronitride, H Rosset, 626, (P III and P IV), The Spectra of Doubly and Trebly Ionised, Miss M. O Saltmarsh, 517, The Glow of, H. J. Emeléus, 460
Photo-electric Cell, The Use of the, for certain Measurements in Industrial Photometry, R. Jouaust and P. Waguet, 251, Cells for Colour-matching, Sir J. E. Petavel, 875
Photographic Plate. Estimating the Qualities of a, T. Thorne Baker, 264, The Law of Blackening of the, at Low Densities, E A Baker, 214, The Progress of Development of a, L. F. Davidson, 172, Plates, Testing, 352
Photographies documentaires, Catalogue de, J Boyer, 472
Photosynthesis, The Physiology of, Sir J C. Bose, 44
Photo-voltaic Elements, The Surface Phenomena in, with a Fluorescent Liquid, A. Grumbach, 787
Phylogeny as an Independent Science, Prof. V Franz, E. W. M, 799
Physical and Optical Societies' Exhibition of Apparatus, The, 100; Science, The Ideal Aim of, a Lecture delivered on November 7, 1924, before the University of London, at King's College, Prof. E. W. Hobson, 797; Society of London election of officers, 348; Prof. W Wien elected an honorary fellow of the, 312
Physician, A Great, 562
Physics: Bibliographies of, issued by the U S National Research Council, 920; in the Rubber Industry with Special Reference to Tyre Manufacture, Dr. W. Makower, 774; Institute of, annual report of the, Sir William Bragg elected president, 884
Physikalischen Gesellschaft, Berlin, the history of the, 241
Physiological Standardisation, 353

Physiologie, vergleichenden, Grundriss der, Prof W. von Buddenbrock. Erster Teil, 938
Physiology: A Text-book of, Prof H. E Roaf, 412; and Pathology, The Teaching of, 412, and "Vital Force," Prof D. Fraser Harris, 608; during the Sixteenth, Seventeenth, and Eighteenth Centuries, Lectures on the History of, Sir Michael Foster Second impression, 45; for Zoologists, 938
Physique générale, Travaux pratiques de, Prof. H Olivier Première série, 224
Phytophthora infestans of Potatoes, The Physiological Aspect of the Incidence of, E J Collins, 106
Pigmentary Effector System: The, a Review of the Physiology of Colour Response, Dr L T Hogben, 147
Pigmentation of Animals, The, Prof. J Barcroft, 679
Pinhole Photography, B. K Johnson, 678
Pitching Folds, The Dissection of, A H Cox, 518
Plagioclases. La Détermination des, dans les coupes minces, 148, Les méthodes de Fédorof et leurs applications à la détermination des, L. Duparc et M Reinhard, 148
Plaice: English, Investigations in the North Sea, 1921–1923, J. O. Borley and D E Thursby-Pelham, 969; The Mortality of. Dr W. Wallace, 337, 607, Dr G P Bidder, 495
Planetary Radiation and Planetary Temperatures, New Measurements of, W W Coblentz and C. O. Lampland, 590
Planets, Minor, 134
Plankton at Cullercoats, Miss Jorgensen, 583
Plantae Novae Sinenses, Dr. H Handel-Mazzetti, 996
Plant: Hunting, The Romance of, Capt F K Ward, 10, Illustrations, New, 351, "Virus" in Vitro, Cultivating a, P K Ohtsky, 315
Plants: Flowering, The Biology of, Dr M Skene, 9, Sex Transition in, T Mackawa, 583, The Biology of, Dr E. J. Salisbury, 9
Plateau's Spherule, A Kinematographic Study of the Formation of, C R Darling, 250
Platinum and Gold Nuggets, Origin of, Prof S F Zhemchuzhny, 959
Platygaster, Polyembryony in, R W Leiby and C C. Hill, 617
Pleistocene: Fossils from San Pedro, California, T S Oldroyd, 617, Pliocene and, Sir E. Ray Lankester, 337, Vertebrate Fauna of North America, The, Dr. O. P Hay, 278
Pleurotus Eryngii, The Specificity towards their Supports of the Fungi of the Group of, L Lutz, 695
Pliny's Natural History, The Identity of "Alumen" in, K. C. Bailey, 764
Pliocene and Pleistocene, Sir E Ray Lankester, 337
Plotz, Ella Sachs, Foundation, Report of the, 507
Poetic Expression in Scientific Fields, Plea for, 58
Poisonous: Plants and Live-stock, Dr. J Burtt-Davy, 438, Substances, An Apparatus for the Investigation of the Effect of, and Mixed Vapours on Catalytic Activity, F. H. Constable, 966
Polar: Aurora, The, Prof. L Vegard, 959, Research, gift for, from the Captain Scott Memorial Fund, 683
Polarisation of Light from the Sky during the Solar Eclipse of January 24, Prof. A Trowbridge, 260
Polarised Light, The Selective Photo-chemical Action of, I., Prof E C. C. Baly and Dr Elizabeth Semmens, 821
Polonium: the α-rays of, The Homogeneity of the Initial Velocities of, Mlle Irène Curie, 626, The Initial Velocities of α-rays from, Mlle I Curie, 887; The Particles of Long Range emitted by, Mlle. Irène Curie and N. Yamada, 967
Polymers, The Magneto-chemistry of, P. Pascal, 590
Pontificia Accademia Delle Scienze Nuovi Lincei, Academy Week of the, 849
Population and Evolution, 406
Portland Cement, A Hundred Years of, 1824–1924, A C. Davis, 150
Positive: Electrical Drift in the Air, The, Dr. W. C. Reynolds; Dr. C. Chree, 531; Flash in Vacuum Discharge Tubes, On the, Prof. R. Whiddington, 358; Rays, Recent Researches in, Prof. W. Wien, 780
Posture and Rest in Muscular Work, The Effects of, Miss E M. Bedale; Dr H. M Vernon, 319
Potash-oligoclase from Mt Erebus, South Victoria Land, and Anorthoclase from Mt Kenya, East Africa, E D Mountain, 858
Potassium and Sodium Cyanides, The Purification of, Grandadam, 1000, Chlororuthenates, The, R Charonnat, 895, The Spectrum of, excited during its Spontaneous Combination with Chlorine, L. A Ramdas, 533; Vapour, The Ionisation of, under the Influence of Visible Light, A Arnulf, 894
Potato Varieties and their Synonyms, The names of, 614
Potatoes, Seed, Cutting, Prof J H Priestley and G. C Johnson, 350
Poultry, Change of Linkage in, with Age, J B S. Haldane and Dr F A E Crew, 641
Power Alcohol from Tuber and Root Crops in Great Britain, 890, Zones, the Mapping of Great Britain into, 469
Praseodymiferous Chlorovanadinite, Synthetic, G Carobbi, 895
Precision Training Gear, Slow Speed, governed from a Distance, P P Schilovsky, 213
Prehistoric Deposit of Solutré (Saône-et-Loire), New Discoveries in the, C Depéret, F Arcelin, and L. Mayet, 141, Man, 151
Preservatives and Colouring Matters in Food, Draft Regulations for the Use of, 301
Preservatives in Food, 217
Primitive Community, The Forces of Law and Order in a, Dr B Malinowski, 270, Hunter, The Religion of the, C Dawson, 958
Primula Hybrids, R J Chittenden, 893, *vulgaris*, The Pollination of, E. M Jones, 554
Probability Integral An Approximation to the, S Krichewsky, 49, Approximation to the, W J. Luyten, 947
Production, Skill in Relation to, L A Legros, 814
Proof Plane, The Evidence of the, J Clark, 63
Prospect Intrusion, The Petrology of the, W A Browne, 555
Proteid Materials, Dry, A New Chemical Reaction of, applicable to Histochemistry, M Romieu, 627
Proteins, The Osmotic Pressure of, The Direct Method of measuring the, G S Adair, 857
Protozoa Counts in Soil, The Influence of the Culture Medium on, Mme J Francois-Perey, 359
Protozoology, Part I, 919
Protuberances, Remarkable, Observation of, L d'Azambuja, 358
Psycho-analysis and Mother-right, Dr B Malinowski, 278, applied to Children, 525, Schools of, 867
Psychological Tests of Mental Abilities, Prof A S Woodburne, 454
Psychology and the Sciences Edited by Dr. W Brown, 832, VIIth International Congress of, held at Oxford from July 20 to August 2, 1923 Proceedings and Papers, edited by the President, Prof C S. Myers, 414
Purkinje, J E., The Physiology Laboratory of, 58
Pyrex Glass, 688
Pyrometers, Thermo-electric, List of, Cambridge Instrument Co., Ltd, 349
Pyrophoric Alloys, Dr. N F. Budgen, 172

Quadratic Forms, The Minimum System of Two, H W Turnbull and J Williamson, 554
Quanta, Electric Forces and, Dr J H Jeans, 346, 361
Quantum. Integrals, The Adiabatic Invariance of the, P. A M Dirac, 322, Radiation, Prof A Lodge, 838, 947, Sir Oliver Lodge, 798, Theory: A Suggested Explanation of the, L. de Broglie, 549; Chemistry and the, Prof H. S. Allen, 452; of Band Spectra, an Application of the, to the First Negative Deslandres Group of Carbon, C. M. Blackburn, 590
Quartz Spiral Springs of, Dr. K Situpas, 943, Prof. C V Boys, 944; Studies on, A. Cavinato, 695; The Variation with Temperature of the Intensity of Reflection of X-rays from, and its bearing on the Crystal Structure, R E. Gibbs, 212
Queensland Cotton, Ratooned, F. Summers, 171

Rabbit, Virus Encephalitis in the, S Flexner, 591
Rabbits, The Occurrence in, of Linkage in Inheritance between Albinism and Brown Pigmentation, W E. Castle, 483
Racial Character, Dr H N Hall, Dr Goldenweiser, 474
Radiation Absorption of, by the Emitting Atom, M. de Broglie and J Thibaut, 439; Influence of, on Ionisation Equilibrium, Dr. J Woltjer, Jr, 534, The Structure of, E C Stoner, 358, Theory, Balfour Stewart's Advances in, Sir Joseph Larmor, 159
Radioactive: Disintegration, The Quantity of Heat given off, in the Form of γ Radiation, during, J Thibaud, 822, Minerals, The Ages of, H. V Ellsworth, 476; Radiations, A Method of Analysis by Absorption of, Mme J S Lattès, 931; Springs in the Region of Velay (Haute-Loire), An Alignment of, A Baldit, 694, The Distribution of, A Baldet, 923
Radioactivity and Geology, Prof J Joly, 851; of Some Springs of Alpine Stations, The, R Castagné, 519; The Origin of, E Briner, 1000
Radio: Communication in Canada, 130, -field Intensities, L. W. Austin, 816, Frequency, Measurement of, Grace Hazen and Frieda Kenyon, 29, -luminescence, Decay and Regeneration of, C H. Viol, G. D. Kammer, and A L Millet, 801, Reception on Frame Aerials A D Cowper, 265, D M Ely, 461, Signal Measurements made during the Solar Eclipse of January 24, 273, Strength, Measurement of, Capt Round and colleagues, 924, Signals during the Eclipse of January 24, Direction of, Prof Merritt, 960; Society of Great Britain, acceptance of the presidency of the, by Sir Oliver Lodge, 25, Transmission round the Earth, T. L Eckersley, 942; Waves over the Earth, The Propagation of J. W Nichols and J C Schelleng, 334; Prof E V Appleton, 382, T L Eckersley, 496
Radiological Research—A History, V E Pullin, 274
"Radiosearch" X-ray Apparatus, Medical Supply Association, Ltd, 314
Radium: -B and Radium-C: A Preliminary Note on a Direct Determination of the Distribution of Intensity in the Natural β-ray Spectrum of, L F Curtiss, 401, The Heating Effect of the γ-rays from, C. D Ellis and W A Wooster, 401; Content of Some Meteorites, A Method of Measuring the Smallest Quantities of Emanation and its Application to the Determination of the, G Halledauer, 520, Emanation, The Quantitative Measurement of, in the Guard Ring Plate Condenser, L Siegl, 519; in Uranium Minerals containing Tantalum, Niobium, and Titanium, Estimation of, Mme P. Curie, 322; Influence of, on the Catalase of the Liver, A. Maubert, L. Jaloustre, and P Lemay, 859, Medical Uses of, 174
Railway Electrification: a Complete Survey of the Economics of the Different Systems of Railway Electrification from the Engineering and Financial Points of View, Prof H F Trewman, 417, Transport, A New Method for the Determination of the Working Costs and a Tariff for, Mlle. Thérèse Leroy, 358
Rainbows. Double, C. O. Bartrum, 16; Moving, G F Wood, 548
Rainfall British, 1923, 491; Correlations in Trinidad, W. R. Dunlop, 192, 802, of 1924, The, 204
Ranunculus, A Unique Feature in the Petal of, and its bearing on the Phylogeny and Taxonomy of the Genus, J Parkin, 893
Rare Earth and Alkali Metals: Double Chromates of, G. Carobbi, 403; Double Sulphates of, F Zambonini and G. Carobbi: I; II., 402; Metals, The Determination and Separation of the, from other Metals. VI., L. Moser and E. Reitschl, 403
Rat Menace, The, 331
Rats and How to Destroy Them; dealing with Rats in a House, Shop, Warehouse, Outbuilding, Yard, Stable, Cow-house, Fowl-house, Pig-sty, Garden, Greenhouse, or Vinery; by a River, Stream, or Ornamental Water; on a Ship, Shooting Estate, or Farm, and in Sewers, M. Hovell, 331
Ray Society, election of officers, 435
Rayleigh, Lord, The Life of, Prof. H. E. Armstrong, 47
Rayons γ de haute énergie et leur effet photoélectrique, Les, Duc de Broglie, 461
Reading, University College, proposed royal charter for, Principal W. M Childs, 892
Reason and Morals: an Enquiry into the First Principles of Ethics, Dr I Levine, 225
Receipts The Book of, containing a Veterinary Materia Medica, a Pharmaceutical Formulary, a Photographic Formulary, E W Lucas and H B Stevens, 760
Reflectors for the Projectors of Motor-cars, The Verification of, A Massat, 519
Reflex Inhibition: Recruitment and some other Features of, E G T Liddell and Sir Charles Sherrington, 445; Remarks on Some Aspects of, Sir Charles Sherrington, 445
Reflexes, Myotatic, Further Observations on, Sir Charles Sherrington and E G T Liddell, 141
Refraction of the Eye including Elementary Physiological Optics, Dr C Goulden, 375
Refractive Index of a Mixture, Prof K Lichtenecker, 924
Refractometer, A Marine, with Double Deviation, A Berget, 590
Refractory Materials Fireclays Analyses and Physical Tests, F. R Ennos and Dr. A. Scott, 295
Refrigerator, A Continuous, Munters and Platen, 960
Rejuvenation the work of Steinach, Voronoff, and others, N Haire, 869
Relativity and Cosmology, 408; Einstein's Theory of, Prof Max Born Translated by H L Brose, 408, Ether and Matter and, Sir Oliver Lodge, 419, of Time, The, Prof F Severi, 547, referred to a Flat Space-Time, C K Venkata Row, 261; The Theory of, Dr L Silberstein Second edition, 408, Theory. D C Miller's Recent Experiments and the, Dr. L. Silberstein, 798, Ether-drift and the, Prof A S. Eddington, 870
Religion, Science and: Rev. J. C Hardwick, 795; Prof J A Thomson, 667
Religious Beliefs, Natural Science and, Dr J. S Haldane, 667
Research Committee, The Imperial, 861
Resin Canals in the Spruce (Piesa), R. B. Thomson and H. B. Sifton, 821
Resinous Media, Turbid Solid, Some Optical Properties of, C Chéneveau, 787
Resonance. Exaggerated, Sir Oliver Lodge, 838, Radiation and the Correspondence Principle, Prof. C. G. Darwin, 81, Radium from Thallium Vapour, On the, Prof. A. L Narayan and K Rangadhama Rao, 534
Respiration of Submerged Plants, Influence of the Dissolved Oxygen Content of the Water on the, A. Hée and R Bonnet, 483

REVIEWS AND OUR BOOKSHELF.

Agriculture, Forestry, and Horticulture:

Bear (Prof F. E.), Soil Management, 152
Carver (Prof T. N.), Elements of Rural Economics, 220
Cockayne (Dr. L), The Cultivation of New Zealand Plants, 44
Cockerham (K. L), A Manual for Spraying, 375
Cunningham (A), Practical Bacteriology: an Introductory Course for Students of Agriculture, 415
Currier (Prof. E. L.), Prof. N. J. Lennes, and Prof. A. S. Merrill, Farm Accounting, 220
Drewitt (Dr. F. D.), The Romance of the Apothecaries' Garden at Chelsea. Second edition, 189
Drummie (A. C.), Practical Forestry: from a Workman's Point of View, 375
Ely (Dr. R. T.), and E. W. Morehouse, Elements of Land Economics, 220
Gray (Dr. L. C.), Introduction to Agricultural Economics, 220
Holmes (H. R. J.), A Short System of Farm Costing, 220
Jones (W. S), Timbers. their Structure and Identification, 601
Koehler (A.), The Properties and Uses of Wood, 327
Miller (Prof. M. F.), The Soil and its Management, 115
Nuttall (G. Clarke), Trees and How they Grow. New edition, 564

Orwin (C. S.), Farm Accounts, 220
Record (Prof. S. J.), and C. D. Mell, Timbers of Tropical America, 595
Ward (Capt F. Kingdon), The Romance of Plant Hunting, 10
Willmott (Ellen), Warley Garden in Spring and Summer. Second edition, 12
Wood (Prof. T. B), Animal Nutrition, 418. The Chemistry of Crop Production Second edition, 259

Anthropology and Archæology:

Browne (Major G St J Orde), The Vanishing Tribes of Kenya: a Description of the Manners and Customs of the Primitive and Interesting Tribes dwelling on the Vast Southern Slopes of Mount Kenya, and their Fast Disappearing Native Methods of Life, 866
Haverfield (Prof. F), The Roman Occupation of Britain being Six Ford Lectures delivered by, now revised by George Macdonald, with a Notice of Haverfield's Life and a List of his Writings, 39
Home (G), Roman York the Legionary Headquarters and Colonia of Eboracum, 39
Kidder (A V), An Introduction to the Study of Southwestern Archæology with a Preliminary Account of the Excavations at Pecos, 907
Norden (H), Fresh Tracks in the Belgian Congo from the Uganda Border to the Mouth of the Congo, 866

Rhind Mathematical Papyrus: The British Museum 10057 and 10058. Introduction, Transcription, Translation, and Commentary by Prof. T E. Peet, 899, 935
Rhizosphæra Kalkhoffi causing Disease of Spruce Firs, M. Wilson, 667
Rhobell Fawr District (Merionethshire), The Geology of the, A K Wells, 286
Rhodesia Human Remains from Ancient Gold Mines in, Sir Arthur Keith, 62, Stone Implements in, The Sequence of Types in, N Jones, 777, Southern, The Geology of, H. B Maufe, 584, Weather in, 245
Rhodium, On the Density of, Sir Thomas Kirke Rose, 662
Rhododendrons from Kweichou, China, 993, Silver Leaf on, A D. Cotton, 316
Rice Institute, Houston, Texas, Dr H A Wilson reappointed professor of physics at the, 928
Richards, Ellen, Research Grant, award of the, to Miss Katherine MacFarland Chamberlain, 811
Rickets, The Pathogeny of, L Blum, M Delaville, and van Caulaert, 250
River Regulation, Dr Brysson Cunningham, 863
Rivers and Lakes, the Story of their Development, M A C Hinton, 673, without Embankments, Regulation of, as applied in the Training Works at the Headwaters of the Rangoon River, Burma (locally known as the Myitmaka Training Works), F A Leete, assisted by G C Cheyne, 863
Roads, An Automatic Method of Drawing, A de Cavarlay and D Desacres, 626
Robert the Bruce King of Scotland, The Skull of, Prof Karl Pearson, 303, The Skull and Ancestry of, Sir Arthur Keith, 303, The Skull of, Prof Karl Pearson, 571, Sir Arthur Keith, 572
Rock Salt, Photo-electric Conductivity in, Drs B Gudden and R Pohl, 923
Rocks, The Natural and Artificial Permanent Magnetisation of, F Loewinson-Lessing and V Mitkewitch, 663
Roda, The Meteorite of, A Lacroix, 286
Roman Britain, 39, York the Legionary Headquarters and Colonia of Eboracum, G Home, 39
Röntgen Rays, Action of the, on Cholesterol, A F Roffo, 323
Röntgenspektralanalyse, Tabellen zur, Dr P Gunther, 565
Rose Shoots, Dying-back of, W J Dowson, 394
Ross and Cromarty, Prof W. J Watson, 492
Ross Barrier, The, C S Wright, 175
Rotating Disc, The, P Franklin, 823
Rotation, Very High Speeds of, The Realisation of, F Henriot and E Huguenard, 930
Rotatory Dispersion, 171
Rotorschiff, Das, und seine physikalischen Grundlagen, J Ackeret, 462
Rotor Ship, The, and Aeronautics, Prof I. Bairstow, 462
Rowett Research Institute, Aberdeen, gift to the, by D Webster, 882
Royal Academy Exhibition, The, 878, Asiatic Society, presentation of the gold medal of the, to Prof A H Sayce, 809, Astronomical Society, Dr J H Jeans elected president of the, 275, College of Surgeons of England, award of the honorary medal of the, to R H Burne, 97, Geographical Society award of medals of the, 545, election of officers, 956; Institution, new honorary members of the, 1016, Meteorological Society, 657, Microscopical Society, election of officers and council, 242, Military Academy, Dr W Makower appointed professor of science in the, 176, Astronomical Society, award of the gold medal of the, to Sir Frank Dyson, 168, Society Conversazione, The, 819, Early Activities of the, T E James, 145; Early Science at the, 34, 69, 105, 140, Experiments of, from the Steeple of Old St Paul's, 310; On the Life Statistics of Fellows of the, Sir Arthur Schuster, 389, 400, Publication grant, proposed increased provision for the, 275; recommended candidates for fellowship of the, 310; sale of early printed books by the, 504, 683, of Arts, award of the Albert medal to Sir David Prain, 957, of Edinburgh, award of the Gunning Victoria Jubilee prize to Sir J J Thomson and the Makdougall-Brisbane prize to Prof H S Allen, 775
Rural Economics, Elements of, Prof. T. N. Carver, 220
Russia Science in, 397; The Soviet Government of, and the Protection of the European Bison, etc, 349
Russian Academy of Sciences: Dr. L A. Bauer elected a corresponding member of the, 312, Prof F Soddy elected a corresponding member of the, 545; Prof. H. Fajans nominated a corresponding member of the, 856

Sahara, Eastern, The Stone Age in the, Capt. M Prevost and Dr L Mayet, 509
Sahli's Hæmometer, A New Standard Solution for, A. K. J. Koumans, 946
St. Andrews University: W W McClelland appointed Bell professor of education; Prof A E Taylor appointed Gifford lecturer for 1926–27, 479; forthcoming conferment of honorary degrees, 515, Prof D Jack appointed an assistant in the department of Natural Philosophy, 891
St. George Expedition, The, 133
St. Paul's, Old, Experiments of the Royal Society from the Steeple of, 310
St Piran's Year Book for 1924, 444
Sainte-Gertrude, Holland, Recent Excavations at the Neolithic Site of, Nina F Layard, 859
Salamander, A Neotenous, from Japan, M Sasaki, 654
Salmo salar, The Relation of Sea Growth to the Spawning Frequency in, W L Calderwood, 482
Salps and the Herring Fishery, Prof W C McIntosh, 911
Salters' Institute of Industrial Chemistry, Work of the, 772
Salts Complex, Dr W Thomas, 332, Organic, Electrolysis of some, D A Fairweather, 246
Samoa, American, Parts 1, 2, 3, Prof W A Setchell, 600
San Blas Indians, The, A F Loomis, 992
Sand-hills, The Pressure of, F M Exner, 35
Sands and Crushed Rocks, A B Searle, 2 vols, 78, and their Uses, 78, Industrial, Catalogue of, A L Curtis, 133
Sanocrysin for the Treatment of Consumption, Prof Møllgaard, 272
Sarmad, The Life of, A Wali, 107
Scarlet Fever, Researches on, G F Dick and Gladys H Dick, 504
Schädlingskunde, Anzeiger fur, Heft I, 652
Schain Comet (1925*a*) found independently, The, C Sola, 822; and Reid (1925*b*) Comets, Observations of the, Mlle O Jasse, P Chofardet, 787
Science and Administration in East Africa, 37, Prof J. W Gregory, 753, and Creation the Christian Interpretation, Rev. Dr C F D'Arcy, 795, and Invention, Masters of, F L Darrow, 331, and Philosophy, L J Russell, 70; and Religion, Rev. J C Hardwick, 795, Prof J. A Thomson, 667, and the Community, 4, Dr G Martin, 122; and the Instrument Industry, 209, Chats on, Dr E E Slosson, 561, for the Public, 561, Forthcoming Books of, 440, in Russia, 397, Keeping up with Notes on Recent Progress in the Various Sciences for Unscientific Readers Edited by Dr. E E Slosson, 561, Masters' Association, Annual Meeting of the, 102, Mediæval Studies in the History of, Prof. C. H Haskins, 599, Men of, and Power in the State, Dr A D Little, 4; Philosophy and, 450, Seventeenth-Century, Prof I Irving, 758; The Civilised World's Debt to, President Coolidge and C E. Hughes, 239, to Religion, Contributions of, Rev. S. Mathews and others, 795
Sciences exactes et naturelles dans l'antiquité gréco-romaine, Histoire des, exposé sommaire des écoles et des principes, Prof A Reymond, 673
Scientific: and Industrial Research, Advisory Council to the Committee of the Privy Council for, Dr. J. H. Jeans and Sir W H. Ellis appointed members of the, 274, and Learned Societies of Great Britain and Ireland, The Year-book of the, 1923–1924, 223, and Technical Books, Recent, January 31, Suppt v; February 28, Suppt. iii, March 28, Suppt. iii; April 25, Suppt v, May 30, Suppt. v; Apparatus, Second-hand, Catalogue of, C Baker, 991, Research, Provision for, in the Estimates, 846, Worthies: Ivan Petrovitch Pavlov, Prof. E. H Starling, 1
"Scientist," The word, or its Substitute. Sir Herbert Maxwell; Prof. R A Fessenden, 50; Prof. H E. Armstrong; J W. Williamson, 85
Scientists' Reference Book and Diary, The, 26
Scorpions, the Oogenesis of, Cell Inclusions in, V. Nath, 249
Scotland, Sheet 44, Mull, of the one-inch Geological Survey of, 472
Scottish Anthropometry, Prof. R. W. Reid and J. H. Mulligan, 687
Scylla Serrata Forskal in the Upper Tertiary Beds of Hathab, Bhavanagar, Kathiawar, H. C. Das-Gupta, 931
Sea-bathing, Action of, on the Reaction of the Blood, A. Rabbero, 627
Seals and Penguins, Protection of, by the French Government, 96
Seasonal Forecasting, The Problem of, C L. Robertson, 245
Sea Tides, Deep, Method of measuring, Prof. R. W. Wood, 497
Seaweed, Yeasts, Fats, and Alcohol from, Prof Nadson and others, 63
Secretion, An Introduction to the Study of, Prof Swale Vincent, 293
Sedgwick, William Thompson, A Pioneer of Public Health, Prof R O Jordan, G. C Whipple, and C.-E A. Winslow, 372
Seeds and Bacteria, Symbiosis of, Dr. G J Fowler and Miss R K Christie, 438
Segre's Figure in Space of Four Dimensions, A Transformation of, H F Baker, 357
Seismic Foci, Depth of, Dr S K Banerji, 618
Seismology, The U S Coast and Geodetic Survey to investigate and report on, 615
Seismometry, Absolute, a New Method, Prof P. Kirkpatrick, 530
Selenium and Tellurium, Separation of, V Lenher and C H Kao, 960', Photo-electric Emission of, W. Del Regno, 143
Self -diffusion in Solid Metals, Prof G Hevesy and Mrs. A Obrutsheva, 674, -sterile Plants, A New Interpretation of the Hereditary Behaviour of, E M East and A J Mangelsdorf, 823
Sense Data, The Theory of, Dr H H Plaskett, 350
Serbian Gypsies, Physical Characters of, Dr V Lebzelter, 547
Series Spectra of Two-valence-electron Systems and of Three-valence-electron Systems, I. S Bowen and Prof R A Millikan, 422
Setekh, The God, R. O. Faulkner, 654
Sex Determination, Dr F. A E Crew, 574; Differentiation in the Chick, Minoura, A W Greenwood, 654; Ratios in Africa, Capt. L. W G. Malcolm, 583
Sexualité et hormones. les caractères sexuels considérés comme phénomènes de développement et dans leurs rapports avec l'hormone sexuelle, Prof. C. Champy, 7
Sexuality and Hormones, 7
Shadows in Lighting Problems, Effect of, J W. T Walsh, 242
Shaman, Saiva and Sufi: a Study of the Evolution of Malay Magic, Dr. R. O. Winstedt, 941
Shantung, Cretaceous Fauna and Flora of, H C Tan, 63
Sheep, Black, F W Dry, 351
Silica: of Plants, The, D. R. Nanji and W. S. Shaw, 208, Ware, Fused, 470
Silky Oaks, The Knowledge of the, M. B Welch, 555
Silver and Carbon, Atomic Weights of, Dr G Dean, 246; between Lead and Zinc, The Partition of, W A. Naish, 894; Halides, Magnetic Properties of, A. Garrison, 994, the Anomalous Reflection of, The Effect of Temperature on, M. de Sélincourt, 213
Simplexes doubly incident with a Quadric, On, R. Vaidyanathaswamy, 358
Sind and Baluchistan, Stratigraphy and Palæontology of The Laki Series of Parts of, W. L. F. Nuttall, 929
Single Spark Photography and its Application to some Problems in Ballistics, P P. Quayle, 765
Skeletal Muscles, Extensible Elastic Sinews in, J. Schaffer, 931
Skill in Work and Play, Prof. T. H. Pear, 907
Sleeping Sickness, An International Campaign against, 985
Smectic Bodies and X-rays, E. Friedel, 358
Smoke Abatement League, The, 133; Papers read at a Conference of, 581
Snails, Reversed Symmetry in, Capt. C. Diver, Prof. A. E. Boycott and Miss S. Garstang, 814
Soap: -bubbles, The Bursting of, in a Uniform Electric Field, Profs. C. T. R. Wilson and G. I. Taylor, 70; Solutions, Prof. J. W. McBain and G. M. Langdon, 994

Soaps and the Theory of Colloids, Prof. J W McBain, 805
Sodium Peroxide, Castner-Kellner Alkali Co., Ltd , 393
Soil : Acidity, The Interaction between Silica and Electrolytes in its Relation to Theories of, Prof J N Mukherjee, 157 ; Algæ in Pure Culture, A Study of the Physiology of certain, Mrs Muriel Roach, 624 , Apparatus for the Examination of, Gallenkamp and Co , Ltd., 243 ; in France, A Supposed Sinking of the, C Lallemand, 694 ; Management, Prof F. E Bear, 152 , The, and its Management, Prof M F. Miller, 115
Soils, The Liming and Chalking of, Dr J A Voelcker, Dr J A Hanley, and E M Crowther, 855
Solar , Constant , of Radiation, C G Abbot to lead an Expedition for the Study of the, 772 ; Values, Provisional, Dr C G. Abbot and Colleagues, 957 , Eclipse of January 24 The, 97, 169, 473 , and Wireless Signals, The, Dr W. H Eccles, 260 , Polarisation of Light from the Sky during the, Prof A Trowbridge, 260 ; Radio Signal Measurements made during the, 273
Solenoidal Coils, The Alternating-current Resistance of, S. Butterworth, 177
Solid Nitrogen, Luminescence of, and the Auroral Spectrum, Prof. L Vegard, 837
Solubility at High Pressures, E Cohen and J. C van der Bosch, 511
Solutré, Further Excavations at, Depéret, Arcelin, and Mayet, 394
Solutrean Art, D A E. Garrod, 498
Solvay, Institut International de Chimie, 817
Somerset Oil-shales, H. G Shatwell, A W Nash, and J I Graham, 63
Sound : Production by Insects, F E Lutz, 437 , W S Bristowe, 640 , Waves in the Soil, The Propagation of, Barrè and Schnell, 931
Sounds in Water, The Sensibility of Circular Diaphragms for the Reception of, J. H Powell, 178
South : Africa, The Historical Succession of Cultural Impacts upon, Prof. R A Dart, 425 , African Museum, Report of the, K. H. Barnard, 885 , America, The Ethnography of, seen from Mojos in Bolivia, Baron E. Nordenskiöld, 601 , American Fungi, C Spegazzini, 438 , Australia, The Mammals of, Dr F Wood-Jones, Part 2, 759 , -eastern : Asia, The Mountain Structure and Geographical Relations of, Prof J. W. Gregory, 203 ; Union of Scientific Societies . Annual Congress of the, 652, 995
Soviet Union Review, The, 772
Space and Time : an Experimental Physicist's Conception of these Ideas and of their Alteration, Prof C Benedicks, 408
Spark : Ignition, J. D. Morgan, 352 , Photography, Single, and its Application to some Problems in Ballistics, P. P. Quayle, 765 , Spectra, On the Excitation of, S. Werner, 191
Species, The Origin of, as revealed by Vertebrate Palæontology, Dr. H F. Osborn, 925, 961
Spectacles, Theory of, Introduction to the, Prof O. Henker, Translated by R. Kanthack, 258
Spectra : and Atomic Constitution The Theory of, Three Essays, Prof N. Bohr. Second edition, 559 , The Periodic Structural Regularities in, as related to the Periodic Law of the Chemical Elements, W F. Meggers, 591
Spectral : Frequencies in the Region between Light and X-rays, M. F. Holweck, 618 ; Lines . Forbidden, Excitation of, Dr. P. D. Foote, Dr. T Takamine, and R. L. Chenault, 265 ; Electrically Broadened, The Experimental Control of, M C Johnson, 966
Spectrobolograph, A New Application of the, Royds, 436
Spectrohelioscope, The, Prof. G. E. Hale, 50
Spectrophotometric Measurement of P_H, F Vlès, 554
Spectroscopes, etc., A. Hilger's Catalogue of, 243
Spectroscopic : Binaries, The Nature of, Dr O Struve, 314 ; Parallaxes : Rev. H. Macklin, 921 ; of 520 Stars of Types F to M, W. B. Rimmer, 546
Spectroscopy, Prof. E. C. C. Baly. 2 vols. Third edition, Vol. 1, 153
Speculum Mentis, or the Map of Knowledge, R. G. Collingwood, 79
Sphagnum, Acidity produced in Salt Solutions by, Dr. M Skene and Gladys L Stuart, 605
Spider, A Luminous, B. Brown, 981
Spirilli, The Chemio-therapy of the, Prof. G. Castelli, 66
Spirit of the Wild, The, H. W Shepheard-Walwyn, 941
Spirogyra ? Under what Form do the Tannins exist in, E Michel-Durand, 483
Spirophyra, The Etiology and Structure of the, E Chatton and A. Lwoff, 323
Spleen : in Fishes, The Influence of Life in Salt Water on the Development of the, Mlle France Gueylard, 71 , The Function of the, Prof J Barcroft and others, 397
Sponge-spicules An Orthogenetic Series of Growth Forms in certain Tetraxonid, Prof A. Dendy, 285 , The Origin of , Prof A. Dendy, 190, 459 , Dr. G P Bidder, 298
Sponges from the Southern Seas, Some, 330
Spray Fluids, The Physics of, R M Woodman, 439
Spraying, A Manual for, K L Cockerham, 375
Sprengel Pump, Notes concerning the, J J Manley, 553
Starch and other Cell-contents, W S Iljin, 959
Star Clusters, Open, Absorption of Light in, Dr P. ten Bruggencate, 61
Stark Effect in Metallic Arcs, Prof. N Nagaoka and Y. Sugiura, 476
Stars : Distribution of, with Respect to Magnitude and Galactic Latitude, A New Determination of the, F H Seares and Prof P J van Rhijn, 948 , Evenings with the, Mary Procter, 115 , Fundamental, The New Washington Catalogue of, Prof W S Eichelberger, 582 , in Full Daylight, The Photography of the, M Hamy, 589 , Morning, Interesting Group of, W F Denning, 97 , The Age of the, E Condon, 823 ; The Ages and Masses of the T. Schumann , Dr J H Jeans, 120 , Prof F A Lindemann, 229 , Dr J H Jeans, 297 , E Condon, 420 , the non-Magellanic O-type, The Frequency Distribution on Apparent Magnitude of, E B Wilson and W. J Luyten, 823 ; The Radial Velocities of, The Determination of, M. Hamy, 446 , Variable, with Continuous Variation and Ritz's Hypothesis, C Nordmann and C Le Morvan, 34
Statesman's Year Book, The, 1925, Edited by Sir John Scott Keltie and Dr M Epstein, 941
Statics, Elementary Experimental, for Schools, A P McMullen Revised for the Press, with some additional matter, by E W E Kempson, 332
Statistics, The Mathematical Analysis of, An Introduction to, Prof C H Forsyth, 296
Statue-Menhir from Tramin, South Tyrol, A, Dr O. Menghin, 687
Steam Plants, The Limiting Possibilities in, Prof A. L. Mellanby and W Kerr, 585
Steamship, The Evolution of the, Eng -Capt E C Smith, 167 , to Motor-ships, Conversion of, Eng Lt -Comdr. L J Le Mesurier, 688
Steel after Reheating, The Influence of Tempering on the Mechanical Properties of, L Guillet and A Portevin, 447
Steels Fatigue Strength of, Aitchison and Johnson, 994 , Forging Temperature of, Prof K Honda, 280
Stefansson in the Arctic, With, H. Noice, 410
Stellar Energy The Source of . Prof A S Eddington, 419 ; Dr J H Jeans, 494 ; Spectra, Broadening, Dr W. J S Lockyer, 508 , Spectrophotometry, J Baillaud, 134 , Statistics. III, W J Luyten, 823
Stibamine, Use of, in Kala Azar, Dr Napier, 509
Stimuli in Plants, Transmission of, Sir J C Bose, 49 , R Snow, 82 , Prof. H. H. Dixon, 421 , Sir J C Bose, 457
Stock Poisoning in the Northern Territory, J. Ewart, 287
Stone Decay and Preservation of Buildings, Prof. A. P Laurie, 554, 779
Stonehenge : The Orientation of, E. H Stone, 800 ; The supposed Blue Stone Trilithon, E. H. Stone, 84
Stoney Indians of the Bow River, Alberta, The, L H. D. Buxton, 518
Striated Discharge, The Theory of, Prof A. Günther-Schulze, 549
Stringed Instruments, The Rational Mounting of, A. Broca, 519

Stroboscope, An Experiment with a, Prof. G R Paranjpé, 265
Structures in the Sea, Deterioration of, 244
Sturgeon, William, and the Centenary of the Electromagnet, Prof. J. A Fleming, 847
Sturly, P Custot, translated by R Aldington, 976
Subject Index to Periodicals, The, 1921 B-E · Historical, Political, and Economic Sciences F: Education and Child Welfare, 80
Submarine · Illumination, The Photo-electric Measurement of, Dr H H Poole, 929, Measurements of Gravity, Dr F A V Meinesz, 550
Substance, The Permanence of, Sir Joseph Larmor, 231
Succinea ovalis, Say, Spermatogenesis of, C. P Hickman, 86
"Sucking-fish," The Adhesive Apparatus of the, Dr Sunder Lal Hora, Major R B S Sewell, 48
Suez Canal, The Biology of the, H Munro Fox, 262
Sugar Industry in Great Britain, 352, The Hydrolysis Constant of, H Colin and Mlle A Chaudun, 250
Sugars from the Point of View of the Organic Chemist, Sir James C Irvine, 347
Sulphide Fog produced by Bacteria, M L Dundon and J I Crabtree, 585
Sulphuric Acid Manufacture, 396, The Action of Dilute, upon Fields of Cereals, E Rabate, 71, The Reduction of, to Hydrogen Sulphide, A Vila, 35
Sulphur Vapour, The Absorption Spectrum of, as depending on the Constitution of the Molecules, Dr V Henri and C Teves, 35
Summer Time Bill, The, 434, 545
Sun: and Stars, Atmospheres of the, Convection Currents in the, C E St John and H D Babcock, 26, Observations of the, J Guillaume, 34, 250, 626, The, and Atmospheric Electricity, Dr L. A Bauer, 279, The Eclipse of the, of January 24, 1925, E Esclangon, J Guillaume and Mlle M Block, 358
Sunlight, Natural and Artificial, in Health and Disease, Dr Saleeby, 956
Sunshine and Open Air, their Influence on Health, with Special Reference to the Alpine Climate, Dr L. Hill, 259
Sunspots · and Temperature, A H Wallis, 135, Terrestrial Magnetism, and Atmospheric Electricity, The Relations between, Dr C Chree, 982
Surface · Abrasion as a Potential Cause of Localised Corrosion, U R Evans, 662, Films, The Kinetic Theory of, R K Schofield and Dr. E K Rideal, 999, Tension of Liquids, A Stroboscopic Method of Determining, Prof P N Ghosh and D Banerji, 230
Survival, A Curious, Sir Oliver Lodge, 678
Suspensions, The Effect of Light on the Settling of, C G T. Morison, 786
Swedes and Turnips, The Improvement of, by Breeding, J M F Drummond and F. W Sansome, 661
Swedish Oceanography, 395

Scientific Worthies.

XLIII.—Ivan Petrovitch Pavlov.

THE eminent physiologist, whose portrait is published to-day in continuation of the NATURE series of Scientific Worthies, was born on September 14, 1849, in the district of Rjásan in Russia. He was the son of the village priest. After receiving some education at a theological seminary, he determined to devote himself to science and entered the University of St. Petersburg. On the completion of his course in general science, he took the medical course at the Military Medical Academy, receiving his qualification to practise in 1879. At that time Botkin, the clinician, maintained several younger men as scientific assistants to carry on research in connexion with his wards, and Pavlov, after qualification, became his assistant, with special charge of the work involving animal experimentation. In 1883 he obtained the M.D. of St. Petersburg, and in 1884 was appointed privat-dozent in physiology. Immediately afterwards, he went for two years to Germany to work under Ludwig and under Heidenhain. In 1890 the Institute of Experimental Medicine was built at the cost of Prince Oldenburg, von Anrep being appointed its first director, and in 1891 Pavlov became director of the physiological department of the Institute. In 1897 he was called to the professorship of physiology in the Military Medical Academy, without, however, giving up his post in the Institute of Experimental Medicine, and in 1907 he became one of the four scientific members of the St. Petersburg Academy and obtained in this way another laboratory under his charge. His work from this time forward, therefore, was carried on in three laboratories, his own personal experiments, however, being confined to the Institute of Experimental Medicine, the other two laboratories being in charge of assistants, though the work at all three places was inspired directly by Pavlov and subject to his continual oversight and criticism.

Pavlov married quite young, his wife being a teacher in a school and herself the daughter of a village priest. He has had four children, one of whom is a well-known physicist who has worked in Cambridge under Sir Joseph Thomson and is now professor of physics in Leningrad.

Pavlov's scientific work falls easily into three well-defined chapters, though there is a certain leading idea which has guided him throughout and characterises all the researches for which he has been responsible. He set himself from the beginning to elaborate the analytic method of research Each function of the body has to be studied in relation to other functions as well as to external conditions, and the exact part played by each condition determined by artificial removal or arousal of the condition *while keeping the other conditions constant.* Up to Pavlov's time the necessity for this last precaution had not been properly appreciated or systematically carried out. Physiologists had been content to study functions in isolated organs or in animals in a profoundly abnormal condition, either through the action of anæsthetics or under the effects of discomfort or pain Pavlov realised that these disturbing factors, namely, anæsthetics, pain and discomfort, must be eliminated before the part played by excitation of a nerve, for example, under normal conditions could be appreciated, or proper value given to the results of operative procedure.

We see the beginning of these ideas in the first chapter of Pavlov's scientific activities, those connected with the physiology of the circulation. The first papers published by him in German appeared in 1878–1879 and dealt with the normal regulation of the blood pressure in the dog. In these experiments, Pavlov trained a dog to allow the insertion of a cannula in a small superficial artery on the inner side of the knee-joint and to remain quiet while the blood pressure was recorded. In such an animal he was able to study the effects of digestion as well as of drinking large quantities of fluid in the form of broth. He found that neither of these procedures produced any change in blood pressure amounting to more than about 10 mm. of mercury. In 1887 he published two papers on the efferent nerves of the heart, the first based on work carried out in St. Petersburg, while in the second paper he described the results of testing his previous findings with the use of Stolnikow's apparatus for measuring the output of the isolated heart. This research was carried out while he was studying in Ludwig's laboratory.

The work, however, for which Pavlov is best known is that connected with the physiology of digestion. Here the introduction of new methods devised to fulfil the conditions laid down by him at the beginning of his career enabled him to rewrite this chapter in physiology. At the present time our whole idea of the course of digestion is based upon Pavlov's discoveries. This work would have been impossible but for Pavlov's marvellous skill as an operator. Already in 1879 he had published three papers on the pancreatic secretion, and one of these described a new method which he had elaborated for making a pancreatic fistula, but from 1888 to 1900 all his activities were devoted to the problems of digestion In 1888 he showed that the vagus nerve was the secretory nerve to the pancreas, and also was able to explain why previous observers had failed to obtain any results from stimulating this nerve. In 1889 one of his pupils published a preliminary note in the *Centralblatt fur Physiologie* on the secretion of the gastric juice.

It is in this note that we first find a description of Pavlov's method for obtaining pure gastric juice. The animal was provided with fistulous openings into the stomach and also into the œsophagus. Such an animal had to be kept alive and in good condition by the introduction of food through the lower end of the œsophagus or directly into the stomach. It was essential, according to the rules laid down by Pavlov, that the animal should be kept in good condition, free from pain or even from discomfort. After such an operation these objects can only be attained by devoting extreme care to feeding the animals. At that time there were no proper facilities for the care of animals, and this work could not be entrusted to an ordinary laboratory attendant. Pavlov, therefore, after operating on his dogs, took them home, and here in his small flat they were looked after by his wife, with the children.

The success of Pavlov's experiments was entirely due to the devoted care which was given to the animals. In a dog provided with an œsophageal and a gastric fistula Pavlov found that, within a few minutes of giving the animal food, there was a copious flow of juice through the gastric fistula. This was known as "sham feeding," and the secretion was proved by him to be due to the effect of appetite and was therefore named by him "psychical secretion." It could be aroused not only by eating but also by the mere sight of food, though it ceased as soon as the animal realised that the food was not going to be given to it. Pavlov proved also that the efferent channel for the psychical reflex was by the vagus nerves and that the secretion was stopped by section of the vagus nerves and was aroused by artificial stimulation of the peripheral end of a cut vagus nerve.

From 1892 to 1897 a whole array of papers on the physiology of digestion appeared in the *Archives des Sciences Biologiques*, so that Pavlov's discoveries became known to his colleagues in other countries. In 1897 a collected account of his work was brought out in German

and in French under the title "Die Arbeit der Verdauungsdrüsen." A little time later an English translation appeared from the German edition by Prof. W. H Thompson. In 1904 Pavlov was awarded the Nobel Prize for medicine for his work on the physiology of digestion. By this time, however, Pavlov's methods had become widely known through the agency of his pupils, many of whom had acquired sufficient operative skill to carry out the difficult operations which had previously depended on Pavlov himself, so that the work could be continued on the lines laid down in Pavlov's laboratory. At the date of the award of the Nobel Prize, Pavlov had practically given up a direct personal interest in the subject of digestion and had taken up another subject.

Hitherto, our methods of investigating the functions of the cerebral hemispheres have been extremely unsatisfactory. We may study the effects of removal or excitation of definite areas in the cortex, but the results of such experiments have given rise to conflicting opinions as to their significance We know, for example, that in most mammals all the apparatus necessary for immediate motor reactions is contained in the parts below the hemispheres, and it is difficult to judge from the presence or absence of a response to some sensory stimulation after removal of portions of the cortex whether the cortical deficiency is really responsible for the effects, if any, observed More stress has been laid, therefore, on observations on man, where lesions have been produced in the cortex by disease or injury. Here, however, there is a tendency to abandon the pure physiological method, and in our arguments we are apt to jump continually from the objective to the subjective method and vice versa.

Physiology is the objective examination and analysis of the behaviour of an animal under all manner of conditions. Up to the time when Pavlov began his researches, we lacked such objective physiological methods as would do for the analysis of the functions of the cortex the same services that had been rendered by physiological method in the hands of Sherrington for the analysis of the spinal reflex functions, or which have recently been used by Magnus and others in the investigation of the manner in which equilibrium is maintained or restored. We know that the cerebral cortex is what has been called the educatable part of the central nervous system: it is responsible for reactions which have been learnt in the course of the individual's existence. In the higher animals, especially in man, these learnt reactions overlie and take precedence of most of the immediate reflexes carried out by the spinal cord and brain stem, so that almost the whole of a man's behaviour throughout his adult life is carried out by a series of reactions to the environment for which the cortex is primarily responsible. An analysis of the manner in which this complex never-ending series of reactions is built up so as to form an individual with his peculiar reactions, must begin with the simplest.

Pavlov conceived the ingenious idea of using the appetite reactions, with which his previous twenty years' work had made him so familiar, as an objective sign of cortical reactions. It is well known that introducing acid or other gustatory substances into the mouth of a dog evokes a flow of saliva, and the intensity of the reaction can be measured by providing the animal with a salivary fistula and counting the drops or measuring the amount of saliva which is secreted in response to a given stimulus. Such a reaction is called by Pavlov an *unconditioned reflex* If, however, some other kind of stimulus, for example, ringing a bell, be associated for some time—weeks or even days—with the presentation of food or the introduction of acid into the mouth, the associated stimulus after a time is sufficient to evoke a flow of saliva without the presentation of food This reaction was called by Pavlov a *conditioned reflex* It is dependent on the laying down—the "education"—of new paths in the cortex This method of establishing new reflexes has been used by him for investigating the higher functions of the cortex, the conditioned salivary reflex being employed as the unit sign of cerebral activity, just as the movements of flexion or extension of a limb have been used as a test for spinal function. Instead of studying the physiology of the eye, the ear, and other superficial organs, in its purely subjective aspect, we can use any of these sense organs for the establishment of a conditioned reflex or reflexes. We can proceed, untrammelled by psychological preconceptions, to study the behaviour of animals in its highest aspect by purely objective methods.

A preliminary account of his researches was given by Prof. Pavlov in the Huxley Lecture which he delivered at Charing Cross Hospital on October 1, 1906. Since that time a very large number of researches carried out by this method have been published by Pavlov and his pupils, but almost entirely in Russian, so that they are very little known, except in broadest outline, in Great Britain and other countries. It is satisfactory to learn that he is now engaged in writing a collected account of these researches which, when translated, will make them available for the instruction of physiologists, as well as psychologists, throughout the world, and will enable us to attack by this new method and with a greater hope of success the function of the cerebral hemispheres, which is indeed the capital question in the physiology of man.

Pavlov was elected a foreign member of the Royal Society in 1907 and was awarded the Copley Medal in 1915.

E. H. STARLING.

Science and the Community.

IN an address delivered in connexion with the recent celebration of the centenary of the Franklin Institute, Philadelphia, and published in the Journal of the Institute for November, Dr. A. D Little directs attention to the curious anomaly that although all the distinctive features of modern civilisation are due to discoveries made by scientific men, yet in no country in the world is the governing and directing power in their hands. It is an interesting but very familiar fact. Dr Little, in his own engaging and energetic style, is only saying over again something that has been said by various eminent men of science for very many years. It is a fact that not more than 100,000 men throughout the world are creatively engaged in the advancement of science, and yet a list of those features of our modern civilisation which distinguish it from the middle ages would show that they are dependent upon these men and could not continue without them Nevertheless, the opinions of scientific workers are not asked on the direction of the civilisation that their kind have built up, nor are their services considered worthy of any special reward.

At first sight this state of affairs appears to be fantastic. Dr. Little vividly illustrates the astonishing disparity between service and award in a modern community:

"It is incomparably more profitable to draw The Gumps for a comic supplement than to write 'The Origin of Species.' There is more money in chewing gum than in relativity. Lobsters and limousines are acquired far more rapidly by the skilful thrower of custard pies in a moving-picture studio than by the no less skilful demonstrator of the projection of electrons. The gate receipts of an international prize fight would support a university faculty for a year"

All this is, of course, quite true, but the implications are a little doubtful. Is it suggested that Einstein should be paid more than the custard-pie expert, or that the expert's income should be reduced below the level of that of a professor of physics? The custard-pie expert is paid directly by the public; for the amusement he gives them they pay him an immense income. But the professor of physics does not amuse them, for the most part he bores them, and they are in no position to understand that his work is of real importance to their lives and to the lives of their children.

It seems that Dr. Little is really finding fault with the cultural level of modern communities We may look forward to a Utopia where the proletariat would rather attend a lecture on the tensor calculus than see a comedy by Charlie Chaplin, but we must admit that that time is not yet. A more pertinent comparison would be between the salaries of scientific men and of other public servants, since the value of the work in these cases is not directly assessed by the public.

The implicit claim in the passage we have quoted, that scientific men should be rewarded with gigantic salaries, is probably not intended by Dr. Little, although the confused feeling which gives rise to it is often apparent in discussions on this subject. The money value of work done is, with nearly every kind of work, extremely difficult to assess. Indeed, the problem is probably best defined in the case of the custard-pie expert, since, if a million people (including men of science) are willing to pay a shilling for his performance, it seems that the monetary value of that performance is one million shillings. But who could possibly have assessed the monetary value of Gilbert's experiments in magnetism, or of Euler's researches on elliptic integrals? And what is the *monetary* value of the theory of relativity which, so far, has had no direct influence whatever on the life of the community? But although we think the scientific man is wrong to envy the income of the successful cinema actor, it is true that science has now sufficiently proved its value to enable the scientific man justly to insist on rewards that shall enable him to keep in good health, prosecute his work in proper conditions, and encourage him to produce and rear children. It is established that he and his offspring are a very desirable social asset; and the real injustice and stupidity of those in power are shown in the fact that even these minimum demands are not properly met.

Dr. Little also complains that scientific men are not admitted to positions of power in the community. In spite of the fact that some of them, particularly during the War, have shown themselves possessed of great administrative abilities, scientific men are not invited to co-operate in the task of government. Yet, seeing how much the modern community is dependent upon their labours, it would seem only natural that they should be given a voice in the direction of affairs. But here again we are met by a demand that requires careful consideration. For good or ill, democracy is the prevalent form of government, and, as Dr. Little says:

"An electorate, which regards itself as free, listens to the broadcast noise of manufactured demonstrations and is blind to the obvious mechanics of synthetic bedlam. The result is too often government by gullibility, propaganda, catchwords, and slogans, instead of government by law based on facts, principles, intelligence, and good will."

These are the conditions which result in the appointment of our leaders, and we may take it that the fittest survive. It is not likely that the men who can swim successfully through this welter will have much knowledge of, or reverence for, the scientific attitude of mind. It is too much to expect that they will demonstrate to the whole world their own incompetence by handing over their business to larger and better-trained intelligences. Once more, what is required is a higher cultural level on the part of the public, a general recognition of the value of the scientific mind in all departments of public life. But here we are hampered by the fact that we have no clear evidence that the majority of scientific men would be of any particular use in the conduct of affairs. It is not wise to make claims that cannot be substantiated, and the views of scientific men, taken as a whole, on political questions seem indistinguishable from the views of an equal number of ordinary citizens. With the majority of scientific men their habit of cautious weighing of evidence, their ingenuity in reducing a problem to its essentials, their lack of prejudice in coming to results, do not noticeably extend to their political opinions. They read newspapers as uncritically as does any other kind of educated man, and far more uncritically than the most insignificant Fleet Street journalist. There is no evidence that the views of the Royal Society on international politics are worthy of any special consideration

While, however, it is true that scientific men, as a whole, rank with the rest of the community in these questions, it may be that there are branches of science in existence which could make valuable contributions to the actual problems of government. This is obviously true of problems which involve technical processes. A general scheme of electrification, for example, should obviously be committed to men of science. Questions concerned with national defence, also, should be, and largely are, in the hands of scientific men. But Dr. Little thinks that men of science could make still more fundamental contributions. He refers us to psychology, and apparently thinks that its findings could already be profitably applied to the general problems of government. This may be true, although it seems likely that the science of psychology should be further developed before any body of legislators should be encouraged to attempt striking improvements by its aid. Undoubtedly science can already furnish much besides "practical applications," but chiefly, we suggest, in giving problems a new orientation and by suggesting new methods of attacking them.

There is another aspect of the general question, an aspect that Dr. Little has not touched upon. Granted that some scientific men possess great administrative ability and that they could play a very effective part in solving problems now left to the politicians, do we want to use our scientific men as administrators? In the United States they are already employed in that way to a greater extent than is customary in Europe; but whatever the benefit to the American community, it is not clear that science in the United States has benefited by it.

Mr. Bertrand Russell has recently given it as his opinion that, in the United States, Einstein would probably have been made the administrator of a large university and, as a consequence, would never have had the leisure necessary to develop his generalised theory of relativity. Would that have been a gain? Was it a gain that Newton should have become an industrious and conscientious Master of the Mint, seeing that he produced no more original work in science for the rest of his life? Newton's work in science certainly saved the labours of two or three generations of scientific men. It is difficult to say when the theory of relativity would have been hit upon if Einstein had devoted his time to other things.

It is not at all clear that a scientific man, as soon as he has proved himself to be of great value to science, should be immediately called upon to do something else, even though the something else should be of more immediate practical utility. Dr. Little informs us that American men of science are not in Congress. Well, they are presumably in their laboratories, which may ultimately be a better thing for the world. Nevertheless, it is desirable that so valuable a group should have a means of making the weight of its opinions effective in government

The true issue is that the scientific contribution should be worthily employed. It should no longer be left to random and sometimes base exploitation. This means that scientific men must come into the arena, and take a greater part than they have yet taken in impressing their ideals, as well as their ideas, on the public. It would not be a bad thing if scientific men developed a "class-consciousness." If scientific ideals are to gain any hold on the community it must be by vigorous propaganda, not by annual laments at the paucity of government grants. There should be lecturing campaigns and periodicals devoted solely to this end. As it is, the writers quoted by Dr. Little are able to say, with some show of justice, that science touches only the fringe of life, that it has no bearing on the centre of life at all. In a democracy one must appeal to the people. Science has a spirit as well as a body, and it is its spirit, even more than its body, which is the potential saviour of mankind.

The Study of Crystals.

(1) *X-rays and Crystal Structure.* By Sir W. H. Bragg and Prof. W. L. Bragg. Fourth edition, revised and enlarged. Pp. xi + 322 + 8 plates. (London: G. Bell and Sons, Ltd., 1924.) 21*s.* net.

(2) *The Structure of Crystals* By Ralph W. G. Wyckoff. (American Chemical Society Monograph Series.) Pp. 462. (New York. The Chemical Catalog Co., Inc., 1924.) 6 dollars.

(3) *Chemische Kristallographie der Flüssigkeiten: Kurze Anleitung zur Synthese und Untersuchung polymorpher und kristallin-flüssiger Substanzen.* Von Prof. Dr. D. Vorländer. Pp. 90 + 30 Tafeln. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1924.) 12 marks.

IT is only about twelve years ago since the study of the crystalline state was the most neglected of all the branches of physical chemistry, so much so that a student who was full of learning about ions and about osmotic pressure would probably be unable to define a centre of symmetry or to describe the meaning of hemihedrism, unless he happened incidentally to have been also a student of mineralogy. The marvellous changes which have taken place in recent years have been due almost exclusively to the new methods of studying crystals by means of X-rays, which were discovered by Laue in 1912, and developed without delay by the Braggs. Some fifty-seven papers on the subject were already published in the year 1913, and it was only the diversion of scientific energy to other ends during the War period that kept the output for several years below thirty papers per annum. Since then, as Dr. Wyckoff's bibliography shows, the output has increased to such an extent that on the average two new papers on the subject are now being issued every week.

(1) In the midst of all this activity it is only fitting that a fourth revised and enlarged edition of the book on "X-rays and Crystal Structure," first issued in January 1915, should appear. It is remarkable that, in spite of the great developments that have taken place, this book still retains the charming simplicity of style which enables Sir William Bragg in his lectures to persuade even the simple and the unlearned that learning is both possible and pleasant, even when the subject to be learnt is the science of crystallography. The contents of the book are, however, changed almost beyond recognition, not merely by the inclusion of new matter, but also by the introduction of new types of investigation. Foremost amongst these is the application of X-rays to the study of the structure of organic crystals, where the method only indicates directly the spacing and orientation of the *molecules*, leaving the positions of the *atoms* to be deduced from a blending of stereochemistry with crystallography. In this difficult field caution is obviously needed; but not that type of caution which leads to pessimism, or to a refusal to undertake experimental investigations on the ground that the methods available are wholly inadequate to the task. It is, however, in strict agreement with the facts of chemistry that Bragg regards the diamond as the prototype of all saturated carbon compounds of the "aliphatic" series, and "graphite" as a prototype of the bewildering "aromatic" series, where a latent unsaturation lies concealed beneath a superficial appearance of saturation, like a bankrupt hiding his financial necessities from all but his most intimate friends.

Having thus secured, by the X-ray analysis of diamond and of graphite, a direct foothold in carbon-chemistry, Sir William Bragg and his colleagues have attacked a series of problems of increasing difficulty; and if the results of their investigations have not the same adamantine certainty as in the case of the elements and their simplest compounds, they have been in the highest degree useful to chemists, stimulating them into activity of thought and investigation by means of new conceptions of "chemistry in space," and by the presentation of new problems. It is indeed refreshing to see elementary sulphur treated with the organic compounds and to realise that it has after all most of the characteristics of such compounds, and to see the familiar tetrahedral model of the carbon atom used, with a sound basis of experimental fact, to explain the arrangement of the silicon atoms in quartz. Chemists would be ungrateful if they failed to welcome such intrusions from the most helpful and sympathetic amongst their physical colleagues.

(2) Dr. Wyckoff's book, although addressed to chemists, as one of a series of monographs prepared for their edification at the request of the American Chemical Society, is much inferior in its power of appeal, since no attempt is made to present the story in an easy or simplified form. Even on the first page the reader is presented with a definition of a screw axis of symmetry, of which the familiar rotational axis is treated as a special case, in direct opposition to the humane method of teaching which consists in leading up from the known to the unknown; and already on the fifth page he finds himself entering a thick forest of point groups, beginning with "Point group 1C(C_1) [Hemihedral class]." No apology is therefore needed for the statement that the book would be hard reading for a chemist who had already studied crystallography, or for the advice that a reader who is ignorant of crystallography would do well to buy an introductory text-book on the subject, and master it before tackling

Dr. Wyckoff's monograph. The book is, in fact, suitable as a guide to a research worker taking up the study of the subject, and it will be welcomed by the more mature workers in this field on account of the complete bibliography which it contains; but it is quite unsuitable for the general reader, who would find it more profitable to allow the Braggs to explain to him the methods and results of the new processes of analysis.

This does not mean that the book is of no value to the chemist; but rather that he must chew hard in order to extract small scraps of nourishment from this very strong meat. Thus it is interesting to be told that in the alums "three of the oxygen atoms in the sulphate group are geometrically alike but different from the fourth, and that the water molecules fall into two groups of six each," since this agrees with the distribution that one would picture in a double sulphate of a univalent and a tervalent metal. Still more fascinating is the statement that, in the ammonia alums, the only arrangement of the four hydrogen atoms which is consistent with the crystal symmetry is a linear one with a nitrogen atom in the centre of two pairs of hydrogens. Since this is chemically improbable (not to say impossible), it is suggested that "the ammonium group functions crystallographically as well as chemically as a single entity, and that its hydrogen atoms need not therefore occupy positions which conform to the demands of the crystal symmetry. This hypothesis probably cannot be directly tested either optically or with X-rays because it is unlikely that the hydrogen nuclei are centres of electron motions" (p. 363) It is, however, noteworthy that, in Morgan and Bragg's analysis of the crystal structure of basic beryllium acetate, the univalent methyl groups are placed with their carbon-to-carbon bonds in the line of the axes of *two-fold* symmetry, in spite of the fact that the three hydrogens of the methyl group demand instead an axis of *three-fold* symmetry. It looks, therefore, as if, in the theory of crystal structure, hydrogen again occupies an unique position, and requires to be treated differently from all other elements.

Dr. Wyckoff devotes a chapter to "Incomplete Crystalline and Non-crystalline Diffraction Phenomena," in the course of which he refers to the so-called "liquid crystals." It is now clear that these queer anisotropic liquids cannot be assigned to any known or theoretically possible class of crystals; but since they also have been subjected to analysis by X-rays, it will not be entirely out of place to include in this review a brief notice of a monograph of ninety pages by Prof. Vörlander (3), whose name has been associated, during a period of nearly twenty years, with work on the chemical aspects of this fascinating subject. So long ago as 1906–7, Vörlander showed the importance of a linear structure of the molecule for the development of anisotropy in the liquid state, and proved that in derivatives of benzene the substituents must be in the *para* position in order to produce this effect, which disappears in the case of the isomeric *ortho* and *meta* compounds.

The present monograph, under the somewhat misleading title of "Chemical Crystallography of Liquids," proceeds along similar lines, the fundamental proposition that anisotropy in liquids implies a linear molecular structure being applied as a test of the molecular form of a large variety of compounds. It is shown, for example, that where a normal propyl and a normal butyl derivative of *p*-azoxycinnamic acid have a range of stability in the anisotropic state of 112° and 103° respectively, the *iso*-propyl and *iso*-amyl derivatives, with branched chains, have a range of only 35° and 42° respectively. It is, therefore, definite evidence of the zigzagging of a hydrocarbon chain that a single CH_2 group between two aromatic nuclei prevents the development of anisotropy in the liquid, whereas this phenomenon is developed strongly when there are two CH_2 groups, and appears again in a less striking degree when the number of CH_2 groups is increased to four. Since the author claims to have laid down rules which have led to the preparation of 2000 compounds of this type, he is obviously in a very good position to discuss the origin of the phenomenon. It is also desirable to direct attention to the exceptional skill which the author has shown in securing photographic reproductions (unfortunately only in black and white) of his observations. This skill was already manifest in his earliest papers in the *Zeitschrift für physikalische Chemie*, and he has certainly not lost it in the intervening years, since the monograph now under review includes a series of sixty-one beautiful photomicrographs, which would by themselves fully justify the purchase of the book.

T. M. Lowry.

Sexuality and Hormones.

Sexualité et hormones: les caractères sexuels considérés comme phénomènes de développement et dans leurs rapports avec l'hormone sexuelle. Par Prof. Ch. Champy. Pp 376+7 planches. (Paris: Gaston Doin, 1924.) 30 francs.

PROF. CHAMPY is one of the most versatile and rapid of biological workers. Tissue-culture; amphibian metamorphosis; the mode of action of hormones; the theory of sex; growth;—he has touched on and illuminated all these fields within the last few years. In the present volume he presents a thesis, based on various aspects of this work, which

is of considerable importance. Perhaps the best way to show its importance will be to set down a series of the established facts on which it is based, letting them tell their own story, and then criticising some of the more theoretical part of Champy's interpretation.

As everybody knows, the majority of secondary sexual epigamic characters arise in development by the more rapid growth, at one period or other, of some rudiment common to both sexes This may take place once and for all, or regress and recur seasonally Some years ago Pézard very thoroughly analysed the influence of the testis upon the growth of the fowl's comb, and found that whereas the comb of the capon grew proportionately to the rest of the body, that of the bird possessing a testis grew disproportionately. The former type of growth he christened *isogonic*, the latter *heterogonic*. After a certain period of heterogonic growth, however, equilibrium is attained, and growth becomes again isogonic, but at a new level

In various lower forms of life, however, heterogonic growth continues permanently This is true, for example, for the claws of male fiddler-crabs. Thus, the large male fiddler has, not only absolutely, but also relatively, larger claws than the small one Here, by the way, the morphologist meets with a stumbling-block The male fiddler-crab has *no* fixed form. Its form, in respect of the proportions of its parts, is only a function of its absolute size

Next point: in many insects, in spite of the fact that no moulting or growth occurs after the imago stage is reached, a similar phenomenon is found; the absolutely larger individuals possess relatively larger sexual characters This is true of the ordinary male stag-beetle, and to a remarkable degree of the Hercules and Goliath beetles Champy rightly concludes, like his predecessors, that the definitive visible effect is due to a continuous process of growth—the accumulation at a heterogonic rate of some substance responsible for the production of the particular organ.

Secondary sexual characters, however, are not the only ones to show heterogonic growth. That is also found, for example, in the limbs of frog-tadpoles; and here, further, the rate of growth is quantitatively related to the amount of thyroid hormone present.

Then, as Lameere in France, and Geoffrey Smith in England, pointed out, the phenomenon extends beyond the limits of the single species Within a group such as the stag-beetles, the larger *species* on the whole have relatively larger sexual characters than the smaller.

Here we clearly have a mechanistic explanation of much of "orthogenetic" evolution. Granted this particular mode of development for certain organs in a given group, then these organs will tend to become relatively larger in larger species, unless counter-measures are taken. If the course of phylogenetic evolution of the group happens to have run from small to large size, then the organs in question will show an apparently determinate evolution, although the only determinism will, as a matter of fact, be that involved in the single type of developmental machinery possessed by the whole group. This appears actually to have occurred among mammals with the horns of the Titanotheres and the antlers of the Cervidæ.

Champy also points out that the details of the heterogonic organ are usually specific, varying from species to species; while, on the other hand, the type of growth is common to all members of the group. This would imply a fundamental growth mechanism, with different individual genes embroidering the resultant organ in various ways in various species. There is also the fact that highly adaptive sexual characters, such as certain copulatory organs, ovipositors, etc, do not show heterogony, but are of fixed relative size This we take as an adaptation, in that size-variation would interfere with nicely specialised function

Finally, the author gives the results of some interesting experiments he has made on the growth of seasonally recurrent secondary sex-characters in Amphibia in relation to their nutritive condition. In brief, he introduces us to the following conception for organs like the glands in the male frog's thumb-pad, or the crest of male newts, there are two limiting factors involved—first, the testis-hormone; secondly, the nutritive condition of the animal. The hormone is necessary for the appearance of the organ, but is efficacious even in very small quantities (*e.g* when produced by small regenerated nodules of testes after attempted castration); anything above a small threshold-value exerts a constant influence. The actual effect produced when excess gonad-hormone is present, however, depends on the excess of nutriment present. Very fat frogs with a bare minimum of testes retain thumb-glands of maximal size, while unoperated but emaciated frogs show great reduction of the glands, which are sometimes not to be distinguished from those of full castrates. In practice, therefore, nutritive condition is the effective limiting factor. These considerations, as Champy justly points out, vitiate many of the castration experiments that have been carried out on amphibians.

As regards general considerations, it remains to mention two points not touched on by Champy. One concerns the quantitative side of heterogonic growth. Champy gives here some suggestive figures, but far too few to establish any assured law of growth. The reviewer has recently taken the matter up in fiddler-

crabs, and finds that, if y = weight of the male's large chela, w = total weight of the crab, then $\log y = \log b + k \log (w-y)$, where $k > 1$.[1] This gives us a first firm step into the details of the process

In the second place, there is the whole problem of what we may call *minus-heterogony*. In the cases which have so far been considered, we have *plus-heterogony*—organs grow faster than the body as a whole But if the growth-rate of an organ were slower than that of the rest of the body, it would become relatively smaller as the animal becomes bigger. Very little attention has been paid to this problem There seems, however, little doubt that the "degeneration" of the male elements in the female accessory reproductive system, and vice versa, will be found to be not a phenomenon of true degeneration, but of depressed relative growth-rate It is usually not realised what an enormous difference in end-result is accomplished by a small but constant difference in relative growth-rate. In the fiddler-crabs above cited, the male chela grows about 1½ times as fast as the rest of the body, and increases from 2 to 65 per cent of the weight of the rest of the body during growth to a total weight of only 3½ grams With a growth-rate of two-thirds the rest of the body, an organ would be negligibly small in a mammal weighing 100 grams at birth. The same is probably true of very many vestigial organs, which would account for their rudiments usually being relatively much larger in the embryo than in the adult. Putting it in another way, we may say that the biologically simplest way of altering the relative size of an organ in the adult seems to be by altering its relative growth-rate during development. The study of quantitative relations during development will thus develop into one of the keystones of biology, throwing light both upon the mode of action of genetic factors and upon the appearance of adult characters It will stand in the same relation to morphology as does physical chemistry to ordinary inorganic chemistry.

We may conclude by a few detailed criticisms. Prof. Champy has given us that irritating thing, a book without an index. That is a vice more prevalent in France than in Britain; but custom does not make it any more excusable. He has unaccountably failed to make any reference to Geoffrey Smith, whose work, published so long ago as 1905, was one of the earliest and most penetrating contributions to the subject of heterogonic growth. He states that he has been unable to find any case of heterogony in a female secondary sex-character—a statement later qualified in the postscript, where he mentions the elytra of the females of two genera of beetles. The type of growth is, however, common in crabs, where it appears to be universal for the abdomen and abdominal appendages of the females. As regards another point, there seems no reason for abandoning Pézard's term *heterogonic* and substituting *disharmonic* for this type of growth.

The drawings are often rather sketchy, and some of the series of insects not quite so convincing as one would wish, while the section on the respective rôles of spermatogenic and interstitial tissues in producing the testicular hormone has no real connexion with the rest of the book

However, there is no doubt that the book is extremely stimulating, and presents a large number of facts, many of them new, in a way which should excite interest and promote research in an almost untouched and very important field of biology We have no hesitation in recommending it to the notice of systematists, morphologists, and experimenters alike

The Biology of Plants.

The Biology of Flowering Plants By Dr Macgregor Skene (Biological Handbooks Series.) Pp xi + 523 + 8 plates (London: Sidgwick and Jackson, Ltd., 1924.) 16s net

THE title of Dr Skene's book can be interpreted in various ways and, at its widest, would embrace the entire field of botany, this could only be dealt with in the most superficial manner in the compass of a single book Here, however, Dr. Skene has restricted himself to a consideration of the relation of the individual to its environment in the sense usually connoted by the term autecology, more particularly as regards those aspects which might be included under applied physiology In his treatment the author has succeeded in incorporating much of the physiological work of recent years, and in a very readable manner points to its bearing on the life of the plant in Nature. The exposition is in general clear, and if the author has at times failed to steer a middle course between the Scylla of technical expression and the Charybdis of obscurity, he has at least avoided the shoals of ambiguity and misconception.

An elementary account of the soil and its function in relation to the supply of water and mineral salts is the occasion of reference to recent work on the hydrogen-ion concentration of the soil solution, the work of Weaver, Cannon, and others on root systems, and a much too brief reference to the soil organisms. The chapter on assimilation and transpiration rightly occupies a considerable section of the book. The present position of our knowledge respecting the function and regulatory action of the stomata is clearly

summarised. There can, indeed, be little doubt that the *primary* function of the stomata is not the regulation of the passage of water vapour but of the gaseous exchanges involved in respiration and assimilation. This is well shown by the fact that stomatal movement is chiefly determined by changes in illumination and by the observations of Lloyd that the maximum aperture of the stomata is maintained between 8 A.M. and 1 P.M., whereas the maximum period of transpiration begins two hours later and ends an hour earlier. The high osmotic pressure attained by the guard cells in bright light probably ensures their maximum efficiency at a time when the demand for carbon dioxide is greatest, but also involves the well-known fact that the stomata may remain open whilst the rate of transpiration is excessive and the leaf actually wilts. As automatic checks to transpiration the stomata may then fail just when most needed

The account of assimilation deals with the conditions governing the process, particularly with the results of Blackman, Willstatter and Stoll, Lundegardh, Briggs, and so on. In this connexion one may perhaps demur to the acceptance of Lundegardh's interpretation that shade leaves are less efficient in respect of diffusion than sun leaves, since the results he obtained are more probably due to the more efficient use of radiant energy by the shade leaf than the sun leaf. Comparisons on the basis of leaf area are manifestly misleading, but those in which equal weights of fresh leaf have been compared show that shade leaves are often much more efficient than sun leaves in low intensities of light and slightly so in bright light. These results, even allowing for the difference in respiration rates, are scarcely compatible with Lundegardh's assumption of slower diffusion in the shade leaf. The mechanism is possibly connected with the higher proportion of green pigments which the chlorophyll of shade leaves contains and in many cases to a higher chlorophyll content, but other factors are probably involved of which we are at present ignorant.

The succeeding chapter treats of the special modes of nutrition as exemplified in saprophytism, parasitism, and the various mycorhizal relations. This is followed by an account of the mechanical requirements of plants as shown by their gross anatomical features and morphological modifications Reproduction and methods of dispersal, which form the subject of the next chapter, and development, which is the final section, scarcely receive adequate treatment. The work concludes with a bibliography of more than six hundred titles of papers cited in the text, and two indices which might more conveniently have been combined.

In a work covering so large a field the treatment is naturally uneven. The subject of galls, for example, is dismissed in half a page, whilst seed dispersal occupies barely ten pages of type, and the author is clearly more at home in the physiological than in the more morphological aspects of his subject. The pages are nevertheless full of interest, and it is certainly a book which students will find most helpful as indicating the trend of certain aspects of modern botanical thought.

E. J. SALISBURY.

Our Bookshelf.

The Romance of Plant Hunting. By Capt. F. Kingdon Ward Pp. xi + 275 + 8 plates (London: E. Arnold and Co., 1924.) 12*s.* 6*d.* net.

CAPTAIN KINGDON WARD has written a book of considerable interest both to the lover of plants and also to the geographer and traveller, since he is able to show not only the interest which attaches to plant collecting, but also the many difficulties which the good plant collector must overcome in order to be successful. Botanists and keen gardeners are likely to be more interested in his book than the public at large since he naturally has to refer to so many plants by their Latin names. The general reader, however, is amply compensated by the fine set of pictures both of general scenes and particular plants with which the book is illustrated.

The volume is the outcome of three separate journeys in China before the War and of three undertaken during 1919, 1921–22, though the last is the one most drawn upon in the narrative. There is a good map at the end of the volume which enables the reader to follow the author in his wanderings. Those who have received seeds collected by Capt. Kingdon Ward realise that he is a really good collector as his seeds have germinated with remarkable success and he also has the keen eye for plants of interest. Whether they may happen to be "first class" in the idea of the nurseryman or not, they are certainly of value to the botanist.

Capt. Kingdon Ward tries to pretend he is not a botanist and in some ways perhaps he is not, but his early training at Cambridge, with which the writer had something to do, and his inherited tastes from his distinguished father, have given him a love for flowers and a keen interest in the remarkable play on form and structure to be met with in the vegetable kingdom. With the author's second chapter we are not wholly in accord and one would have wished that some things in it had been omitted, but this does not detract from the really interesting and, as he rightly terms it, the romantic side of plant collecting.

The chapters when the author is on the march must be read in full to be appreciated, and no review can cover the ground sufficiently to make the reading of the book unnecessary. There is much to be found in the pages beyond the mere hunting for special plants, and much of value is recorded as to the geology and geography of the regions visited. Capt. Kingdon Ward is a true naturalist and very little escapes his keen eye. The book is enlivened by interesting particulars about the various peoples with whom he came in contact;

nor is the humorous side of his travelling experiences forgotten, though no doubt at the time the humour was not always evident. We feel sure that when the good plants introduced by Capt. Kingdon Ward become better known, his name will rank high in the list of distinguished plant collectors to whom British horticulture owes so much.

Light and Sound: a Text-book for Colleges and Technical Schools. By Prof. William S. Franklin and Prof. Barry MacNutt. Pp. vi+310. (Lancaster, Pa.: Franklin and Charles; London: Constable and Co., Ltd., 1924.) 5*s.* net

Electricity and Magnetism: a Text-book for Colleges and Technical Schools By Prof. William S. Franklin and Prof. Barry MacNutt. Pp xvi+294. (Lancaster, Pa.: Franklin and Charles; London: Constable and Co., Ltd., 1924.) 5*s* net

THE two volumes under notice are revised versions of previous editions, and are said to be suitable "for colleges and technical schools." As regards scope it is somewhat difficult to place them, for according to English standards it is curiously uneven. There are many excursions into topics of a more advanced character than is usual in books of this size (and price), but the treatment is mainly non-mathematical, and has a strong practical or engineering flavour Nevertheless, it is usually so lucid as to repay perusal by the average "pure science" student. The sections dealing with lens imperfections and alternating current are particularly good. On the other hand, the methods given for simple lens calculations might be expected to drive even the engineering student, for whose benefit they have presumably been "simplified," to graphical methods for safety. On the whole, however, if the general viewpoint is acceptable, there will be little to criticise in matters of detail, which are usually accurate and up-to-date. An exception, albeit a trifling one, is the statement that "the most accurate wave-length measurements are made by means of the Michelson interferometer." To the English reader the frequent occurrence of such units as "abohms," "stathenries," and the like will at first be a little disquieting, but he may eventually find in their obvious convenience some compensation for their exotic appearance.

Le Volvox. Par Charles Janet. Troisième mémoire: *Ontogénèse de la blastéa volvocéenne.* Première partie. Pp. 179+planches 5-21. (Macon: Protat frères, 1923.) n.p.

IN this third memoir M. Janet approaches the problem of the ontogenesis of the Volvox blastea (cœnobium). He confines himself to the methods of cell bipartition, but in later works he proposes to discuss variations in the process and special cases. The memoir is an able attack on an exceedingly intricate and difficult problem and contains a wealth of minute detail. The author starts by pointing out the primitiveness of the Volvox cell and how, in his opinion, these blasteas are in large measure representative of the primitive animal cell groups. He then goes on to describe the apparatus by means of which he separates out the minute organisms, and having pointed out the fundamental units of the cell he considers the homologies between the blasteas of plants and animals. Thereafter he examines the divisions of the cells of *Janetosphæra aurea* (Ehrbg.) Shaw, in greater detail. It can be well understood that in such an involved study a comprehensive scheme of terms is required; these the author has supplied as well as formulæ for expressing symbolically the type of generation and the mode of reproduction of the organism under study Assisted by 21 excellent plates containing many figures and diagrams, he traces the various divisions and shows that after bipartitions resulting in 1024 cells, the cells of *J. aurea*, having reached their minimum limits and used up all available reserves, cease to divide and enter into a new phase—the flagellate stage. Throughout, the work is one where questions regarding evolution in the plant world are always kept to the front, for the author's knowledge of plant and animal life permits him to make useful comparisons

A Text-Book of Inorganic Chemistry. Edited by Dr. J. Newton Friend (Griffin's Scientific Text-Books.) Vol. 2: *The Alkali-Metals and their Congeners.* By Dr. A. Jamieson Walker Pp xxvi+379. 20*s.* net. Vol. 7, Part 1: *Oxygen.* By Dr. J. Newton Friend and Dr. Douglas F. Twiss Pp. xxvi +370. 18*s.* net. (London: C Griffin and Co., Ltd., 1924.)

THE two new sections of Dr. Friend's "Inorganic Chemistry" deal with (1) hydrogen, the alkali metals, the ammonium-compounds, and the coinage-group of metals, and (2) oxygen, water, and hydrogen peroxide. The style of the book is now so well established, and so well known, that it is difficult to comment usefully on the individual sections as they appear. The parts now issued appear to be very complete in the information supplied; and the expansion of the section on oxygen to a volume of 350 pages has made it possible to include a much larger number of analytical data than it is now fashionable to quote in a text-book, as well as to deal in unusual fulness with modern work on combustion By contrast, the volume on the metals of Group I. appears to be somewhat abbreviated, since the three metals of the coinage-group are disposed of in little more than 100 pages Illustrations are also used less freely, being limited to a few solubility diagrams, etc., and two line-drawings, thirteen in all. The section on oxygen, on the other hand, is illustrated with some fifty diagrams, and a full-page plate showing the photographs by Burgess and Wheeler of flames near the lower limit of inflammation of methane in air. The homologues of oxygen (sulphur, selenium, and tellurium) are postponed to a later section of Vol VII., whilst the remaining elements of Group VI. will form a separate Part III.

Venereal Disease: its Prevention, Symptoms and Treatment. By Hugh Wansey Bayly. Second edition. Pp. xvii+176. (London: J. and A. Churchill, 1924.) 7*s.* 6*d.* net.

VENEREAL disease, like all infectious maladies, is to be considered from two aspects, those of prevention and treatment. The importance of the former certainly has full recognition in Dr. Wansey Bayly's book, the preface of which is devoted mainly to a defence of the policy of the Society for the Prevention of Venereal Disease. In the first section of the book the author

puts forward a scheme whereby he considers that syphilis could be almost entirely eliminated in a generation. Briefly, it consists in compulsory notification to a special Medical Officer of Health, who visits the victim, ascertains from whom the disease was contracted, and traces that individual. Infected persons are given the choice between treatment at a hospital and attendance on a physician of their own selection. Heavy penalties are attached to the doctor who fails to notify, and to the individual who conveys disease to another before being certified free from infection Such a scheme might, however, defeat its own ends by driving the patient to abstain from treatment altogether or to obtain it secretly and illicitly at the hands of quacks

The sections on symptoms and treatment, which comprise the greater part of the book, are clear, concise and fully up-to-date For the student and general practitioner who have not the time to devote to large text-books, there could not be a better guide.

Abridged Scientific Publications from the Research Laboratory of the Eastman Kodak Company. Vol. 6, 1922 Pp 238+vii. (Rochester, N Y · Eastman Kodak Co , 1923) n p

Owing to the increasing number of communications from the Eastman Kodak Laboratory, it has been decided to issue a volume of abridgments every year. The present volume deals with the papers that were published in 1922, many of which were referred to in our columns when they first appeared These abridgments are not mere statements of the subjects dealt with, but are the papers themselves, shortened somewhat by the omission of some of the details that are not necessary to the understanding of the work done and its results Those specially interested will naturally consult the original publication for fuller particulars and especially for more complete data. The 30 papers included in the volume are classified under the headings of physical and photographic optics , inorganic, organic, physical, and colloid chemistry ; photographic theory, and practical photography The character of the work done is now so well known that it is not necessary to enlarge upon it, except to say that several new instruments are described that have been constructed to enable investigations to be carried further than has hitherto been possible

The Amphibia of the Indo-Australian Archipelago By Prof. Dr P N. van Kampen. Pp xii+304 (Leyden: E. J Brill, Ltd . 1923.) n.p

The Malay Archipelago, consisting as it does of a large number of islands separated in many cases from one another by very deep sea, has yielded many very interesting problems in the science of the geographical distribution of animals Nothing perhaps could afford more useful information in the attempt to solve these problems than a thorough knowledge of that essentially terrestrial and freshwater group, the Amphibia.

Prof. van Kampen, of the University of Leyden, has therefore rendered great service by preparing for the use of students a critical study of the 254 species that are known to occur in the Dutch archipelago together with New Guinea, the Bismarck archipelago and the Solomon Islands. The descriptions of the species are mainly technical in character, but so far as possible an account of the tadpoles and some notes on habit are included. There is a useful synopsis of characters at the head of each family and genus, and there are a few excellent illustrations.

Ophthalmo-Optical Manual. By William Swaine. Pp. v+152 (London . The Hatton Press, Ltd., n.d.) 5*s* net

We welcome the appearance of this little volume, because there is a real need for a practical handbook on the main essentials of sight-testing. In this book the subject is treated in a scientific manner seldom adopted in text-books of this nature. The more recent developments of sight-testing are considered , of particular interest are the corrections required to flat trial-case refraction values when toric and similar lenses are to be used. This was first pointed out by the author and is as yet scarcely appreciated by the average optician The unit planes of such lenses are in quite different positions (relative to the eye) from those of the standard trial case lens, and consequently the refraction values for such lenses have to be materially altered. In addition, a number of very useful tables have been included, and these, together with an exhaustive index, make it a valuable reference book.

Warley Garden in Spring and Summer. By Ellen Willmott Second edition Pp ii+41 plates (London · Wheldon and Wesley, Ltd., 1924.) 10*s*. 6*d* net.

This series of beautiful pictures of a famous garden would have been of some general interest had they been accompanied by a plan of the Warley Garden and some particulars about the plants that are in cultivation there As it is, they are merely a collection of pictures, some of which are of no great merit Among the best are the Alpine primroses, Plate 5, and the Nankeen lilies, Plate 31, but had the actual names of the plants depicted been given, in these and other cases, the volume would have been of far greater value to those interested in gardens.

It is to be regretted that a garden, which has so much charm and is owned by a lady who is so fitted to describe it, is merely illustrated in this series of pictures and all that is of real value is left unrecorded.

Unscientific Essays. By Prof. Frederic Wood Jones. Pp. 208. (London: E. Arnold and Co., 1924.) 6*s*. net.

A man is largely known to his friends by his hobbies, and clearly our author's hobby is to sit and reflect, occasionally feeling himself stimulated to jot down what he feels or has seen. He has a broad experience of the wild, both on sea and land, almost unexplored coral reefs of Malay and deserts of Australia. He liked the natives with whom he came into contact, and frequently he has blended folk-lore into his themes, this being perhaps the most interesting feature of his book. He tells us the crab's secret, and of course he caught a sea-serpent, his account of which we first saw repeated in the daily press with references to his official position as a professor of anatomy. As such, journalists apparently supposed him to have no lighter moments ; his essays are just the thing for our ease.

Effective Wave-lengths of γ-Rays.

One of the difficulties in explaining the results of experiments on γ-rays is our lack of knowledge of the variation of intensity with wave-length in the spectrum of the γ-rays. This has led to the use of "effective" wave-lengths (two, in general, being needed because scattering and absorption coefficients vary with the wave-lengths in different manners), and values have been used, which, although incorrect, apparently help to explain the experimental results. For example, I have pointed out at two scientific meetings (American Physical Society, December 1922, and the British Association, Toronto, August 1924), that if we assume, as has been done by several physicists, that the effective wave-length of the γ-rays is about 0·02 Å.U., the secondary β-rays produced in light elements by the hard γ-rays of radium-C possess far too much energy to be recoil electrons (for the properties of which see a paper by Compton and Hubbard, *Physical Review*, 4, p. 439, 1924). Experimental evidence indicates that these β-rays are not photoelectrons. If they are recoil electrons, the effective wave-length of the γ-rays must be taken as about 0·008 Å.U. in order that we may account, on the quantum theory of scattering, for their observed energy. This result, which was first obtained by a comparison of the relative penetrating powers of the secondary β-rays and the β-rays of radium-E, has led, among other things, to a consideration of the following questions.

1. What proportion of the atoms of an element emitting one or more types of monochromatic γ-rays contributes, on disintegration, to such γ-rays?

2. Is a knowledge of the wave-lengths and relative intensities of the lines in the spectrum of γ-rays sufficient to enable us to determine effective wave-lengths and, with theoretical aid, to interpret the results of scattering and absorption experiments?

3. Is the energy of the secondary β-rays which have been called recoil electrons greater than that given by the quantum theory of scattering?

4. Are the γ-rays of thorium-D always more penetrating than those of radium-C, no matter what the thickness of the absorbing material used?

I am not prepared to answer questions 3 and 4 and cannot give a complete answer to the other two. The simplest case to examine is radium-D. In the course of his fundamental experiments on the line spectra of γ-rays, Ellis (Proc. Camb. Phil. Soc. 21, p. 121, 1922) has shown that radium-D probably emits "hard" γ-rays of wave-length 0·264 Å.U., part of these rays being absorbed in producing the L and M spectra of radium-D, the "soft" rays, of average wave-length 1·06 Å.U. By a comparison of the total ionisations they produce, I find that the energy of the soft rays = ¼ that of the hard rays, and as the energy of a hard ray = 1·06/0·264 or 4 times that of a soft ray (if such expressions may be used), it follows that out of every three hard rays emitted by the nuclei of radium-D atoms, two are absorbed in the atoms in which they are produced. The internal atomic absorption coefficient of the hard rays, assuming them to produce the soft rays in the way mentioned, is therefore 0·67 as compared with an external coefficient of about 3×10^{-21}. Ellis and Skinner have directed attention to the very high values of these internal absorption coefficients. It may be worth while pointing out, in connexion with experiments on the scattering of X-rays, that such a high internal coefficient of absorption is not observed with β-rays.

The energy of the unabsorbed hard γ-rays has been found by ionisation measurements to be 1/150 that of the β-rays of radium-E in equilibrium with the radium-D. Taking the average energy of such a β-ray to correspond to 467,000 volts, of a hard γ-ray to 46,700 volts, a simple calculation shows that only one in every five radium-D atoms emits a γ-ray on disintegration. Radium-D apparently does not emit "white" γ-rays or rays which give a continuous spectrum and so we have fairly complete knowledge about it, but this is not the case with most of the other elements emitting γ-rays.

In a recent paper, Ellis (Proc. Camb. Phil Soc. 22, p. 369, 1924) publishes a table giving some of the lines in the spectrum of the hard γ-rays of radium-C, extending from 0·0453 Å.U. to 0·00557 Å.U. What appears to be the most intense line has a wave-length 0·00867 Å.U., a value not very far from that given above. Such tables, however, even if we knew the relative intensities of the lines, do not enable us to find effective wave-lengths of γ-rays, unless we are certain that only a negligible proportion of the radiation is white. That a large part of the γ-radiation of thorium-D is white, is indicated by the following evidence, to which Ellis (Roy Soc Proc. A, 101, p. 1, 1922) has directed attention. The lowest wave-length found by him so far in the line spectrum of these rays is about 0·014 Å.U., and yet they should have a lower average wave-length than the γ-rays of radium-C, as they are more penetrating (see question 4 above), hence the probability of white radiation of very small average wave-length. In the case of radium-C there is not sufficient evidence, so far as I am aware of it, to come to a definite conclusion about the presence or otherwise of white radiation. The following results have been arrived at.

1. If the secondary β-rays, produced in light elements by the hard γ-rays of radium-C, are recoil electrons, with energy given by the quantum theory of scattering (see question 1 above), the effective wave-length of the γ-rays must be much smaller than that usually accepted. Without going into details, I may state that one can prove from this result that no theory, as at present developed, can account for the properties of scattered γ-radiation.

2. With certain reasonable assumptions, it has been found that the internal atomic absorption coefficient of the hard γ-rays of radium-D is 0·67 as compared with an external coefficient of about 3×10^{-21}, and that on disintegrating, one out of every five atoms of radium-D emits a γ-ray.

3. The number of atoms of an element emitting one or more types of monochromatic γ-rays may be only a small fraction of the total number disintegrating and a large part of the γ-ray energy emitted may be due to white radiation.

4. A knowledge of the wave-lengths and relative intensities of the lines in the spectrum of the γ-rays is not, in itself, sufficient to enable one to determine effective wave-lengths, which can be used to interpret the results of experiments on γ-rays.

I think it may fairly be said that it is very difficult to explain the results of experiments on γ-rays of very small wave-length. Definite answers to questions 3 and 4 would help very much. There is not space here to give fully my own opinions, which I must reserve for a communication elsewhere.

Queen's University,
Kingston, Ont., December 6.

Specific and Latent Heats of Iron and Steel.

In previous letters to NATURE (April 19 and September 20) I gave the results of some experiments on the rate of contraction of heated iron and steel wires, partly commercial steels, and partly of steels formed by heating nearly pure iron in graphite for periods lasting from one to five hours. It was found that even the five hours' heating in graphite did not complete, or even nearly complete, the conversion of iron into steel. A similar and more recent series of trials has now been carried out in which the graphite was replaced by wood-charcoal, from which it appears that the action of the latter is far more rapid than graphite, so much so, indeed, that a wire heated in charcoal for a single minute gives a cooling curve notably different from that of the pure iron.

Some of the results are shown in the accompanying diagram (Fig. 1), where the curves refer to nearly pure iron (4 parts in 10,000 of carbon) and to the same iron after remaining in wood-charcoal at a cherry-red heat for two and a half, five, ten, and twenty minutes, one hour, three hours, and four hours respectively. The greater part of the variation of form occurs in the first half-hour's heating, and the difference between the three-hour and four-hour curves is comparatively small.

In all cases the cooling curves well above and well below the critical temperature (*i.e.* from melting point down to about 800° C. and from 400° C. down to ordinary temperatures) are identical, but the presence of carbon prolongs the time required for the metal to change from the high to the low temperature state.

While this change is proceeding, latent heat is being evolved, and whether the wire rises in temperature and expands (showing what has been called "recalescence") during this process depends on whether the rate of evolution of heat exceeds, or falls short of, the rate at which heat is being lost by radiation and convection.

It has been shown, by experiments previously described in NATURE, that the coefficient of thermal expansion for iron and steel undergoes no discontinuous change at any temperature to which the metal was subjected. Assuming for the present purpose that the coefficient is constant, it will be seen, since the loss of temperature in cooling is proportional to the excess of temperature above the surrounding space, and since also the time taken to cool through a given number of degrees is proportional to the specific heat, that therefore the area contained between the cooling curves and the axis (*i.e.* extension in terms of time) is proportional to the total quantity of heat yielded in the cooling process.

Thus, from the results exhibited in Fig. 1, it appears that

(1) The greater the carbon content of the metal, the longer is the time required to complete the change from the high to the low temperature state, and the lower is the temperature at which the conversion ends.

(2) The greater the carbon content, the less is the total heat necessary to raise the metal from ordinary temperature to anything above 400° C.

(3) The effective specific heat changes continuously while the change of state is in progress, but the change is more and more rapid as the carbon content diminishes, becoming probably instantaneous, or nearly so, for pure iron.

(4) The terminal specific heats (namely, from above 850° and below 400° C.) are very nearly in the ratio of one to three.

All the phenomena presented in the tempering of steel are connected with the change of state, and it seems likely that useful information might be derived from records of the contraction which occurs in cooling if made under standard conditions.

It is worth notice that in all the experiments I have made, a small permanent increase of length has occurred at each successive heating when the iron was nearly pure, but that when the carbon content reaches a certain limit this change vanishes, and is replaced by a small permanent contraction when that limit is exceeded.

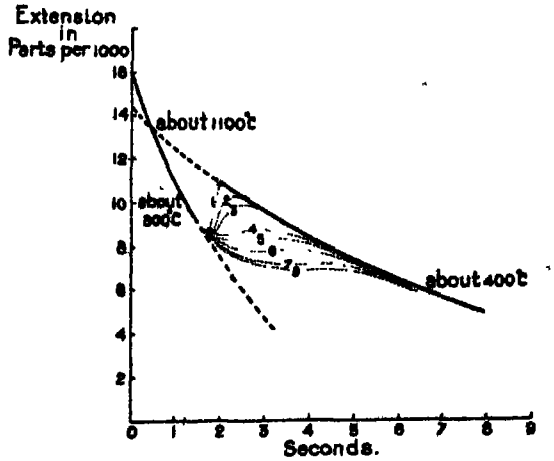

FIG. 1.—Curves showing the contraction of iron and steel wires after heating (by an electric current) in an atmosphere of nitrogen. The iron was produced by the reaction between iron sesquioxide and aluminium. Analysis showed that the metal contained about 4 parts of carbon in 10,000. A small ingot of this iron was drawn into wire of 0·02 in. diameter, and lengths of this wire were heated to a cherry red in wood-charcoal for times specified below. The ordinates of the curves give the extension of the wires at the times indicated by the abscissæ. Approximate temperatures are indicated.

An Endotrophic Fungus in the Coniferæ.

In a communication to NATURE of December 13, Prof. F. J. Lewis directs attention to the discovery of intercellular mycelium in the shoot tissues of *Picea canadensis* and other conifers, and also in roots and shoots of *Ledum palustre* and *Vaccinium Vitis-idæi*. Referring to the two last-named species, Prof. Lewis writes: "an examination of the root and stem of *Ledum palustre* and *Vaccinium Vitis-idæa* from this district has been made, and an endotropic [?endotrophic] fungus has been found similar to that described by Rayner (*Annals of Botany*, 1915) in European material."

The fact that endotrophic mycorrhiza occurs in the *roots* of these plants has long been known and calls for no comment. A full account of the mycorrhiza of *V. corymbosum* was given by Coville in 1911 for American material.

In the paper cited by Prof. Lewis, the present writer described the wide distribution of mycelium throughout the shoot tissues of Calluna and recorded the fact of ovarial infection—implying a like distribution of the fungus—in *Ledum palustre* and *Vaccinium*

Vitis-idæi. A paper now in the press, recording the regular and extensive digestion of mycelium in the mycorrhiza cells of Calluna, contributes additional details respecting the distribution of mycelium in the shoot of Ling and supplies final experimental proof of the identity of the fungus (in the vegetative shoots as in the fruits) with that found in the (root) mycorrhiza.

In view of the conclusions published by Stahl in 1900, the genus Vaccinium is of special interest. In a paper shortly to be published, an account will be given of experimental researches on Vaccinium spp extending over a number of years and evidence supplied that the relation between fungus and vascular plant is even more intimate in this genus than in Calluna. That roots of Vaccinium are infected by mycelium of the endophyte when growing in sterilised soil was overlooked by Stahl,—as more recently by Christoph in the case of Calluna,—because the formation of typical mycorrhiza is partially inhibited in the roots of both these species when growing in a sterilised medium. Under these conditions, the demonstration of mycelium in the mycorrhiza cells demands a more careful technique than was bestowed upon it by either of these observers

The interesting observations on conifers contributed by Prof Lewis confirm the view long held by the present writer, that the distinction between ectotrophic and endotrophic mycorrhizas is one of degree of infection only Many of the so-called ectotrophic forms yield evidence of the presence of intercellular mycelium when a suitable technique is employed This view receives further confirmation from the recent extensive researches of Melin ("Experimentelle Untersuchungen uber die Konstitution und Ökologie der Mykorrhizen von *Pinus silvestris* L. und *Picea Abies* (L.) Karst," *Sonderabd aus myk Untersuch und Berichte*, Bd. II., 1923, Stockholm).

At the same time, it must be pointed out that the presence of mycelium throughout the shoot tissues does not in itself constitute a proof of identity with the mycorrhizal fungus of the same plant Experimental proof of such identity has been obtained for Calluna and Vaccinium, but it is perhaps rash to assume, by analogy, that the same is true for *Picea canadensis* and other conifers

Prof. Lewis's allusion to "symbiosis" raises the question of the exact significance to be attached to this term. In my opinion the term "symbiosis" can be correctly applied to the relationship between flowering plant and fungus in mycorrhiza plants if it is used as originally defined by de Bary. Its use when *mutualism* is implied is justified only if supported by experimental evidence. Each case requires investigation on its merits.

M C. RAYNER.

The Nature of Verse.

THE experimental results reported by Prof. Scripture in NATURE of October 11, p. 534, are of course to be accepted as accurate, but they do not lead inevitably to his conclusions. He is dealing only with "the physical nature of verse," with verse "as it comes from the speaker" and passes to the hearer. Of this he gives a faithful and valuable account; but it is wrong to draw conclusions as to the nature of verse from an inquiry into only one aspect of it.

To express the rhythmical effect of verse Prof. Scripture uses a concept—that of the centroid—which deserves fuller recognition. He states that "The simplest English poetical line consists of a quantity of speech-sound distributed so as to produce an effect equivalent to that of a certain number of points of emphasis at definite intervals." Few will take exception to this, so far as it goes; but he draws the conclusion that verse is "purely a matter of rhythm; it has *no* metre. The usual scheme of prosody with feet, syllables, iambus, trochee, etc., is a fantastic fabric of fancy without the faintest foundation in fact."

A certain amount of poetical work makes no claim to be metrical, but apart from this it is untrue, even on Prof. Scripture's evidence, that verse "has no metre." If the centroids recur at definite intervals then they may be said to mark out measures, bars, or feet, the "point of emphasis" marking either the beginning or the end of the foot. There is no need for the feet to be conterminous with syllables, or to be cut off one from another as if the speech sound were not continuous, or to show any simple or indeed any fixed internal ratio between their parts Prof Scripture may object that this is not the *usual* scheme of prosody, with feet, syllables, etc., that he is attacking. But we may believe in metre without supporting the orthodox prosody of mid-Victorian days. That scarcely needs slaying thrice, although modern metricians who no longer accept it find the old schemes and terminology convenient to use for rough and ready purposes

A more important point is that Prof Scripture takes no account of the fact that the physical rhythm is the external manifestation of a psychological rhythm. One of his examples illustrates this. Whoever read the line from "Hamlet" for him to record evidently felt "is" to be more important than "that," and the record accordingly shows the arrangement of centroids to be

To be or not to be that is the question.

But many, if not most, readers would place the point of emphasis on "that"—

To be or not to be that is the question

the record showing a different arrangement of centroids

The nature of the sound rhythm depends on the nature of the mental rhythm with which it corresponds (or perhaps we may find that they are mutually dependent) Consequently, experimental methods, however accurately carried out, can by themselves reach no finality "The first step in the study of verse," says Prof Scripture, "must be the purely physical one of registering and analysing the air-vibrations" But even if this is so, it is not all We have also to inquire why the vibrations come to be arranged in that particular way The problem of metre is not a merely phonetic problem, for the effect of verse depends not merely on some stimulation of the senses, but on something that is a matter for apprehension on a higher or more complex level than mere sensation, on the *recognition* of some sort of recurrence.

The Origin of the Satellites of Mercury Lines.

INTEREST in the complex structure of the important lines in the arc spectrum of mercury has been revived by the suggestion of Nagaoka, Sugiura, and Mishima (NATURE, March 29, 1924) that the satellites are due to isotopes of mercury. The suggestion is based on the agreement of the wave-lengths calculated according to a hypothetical formula (similar to Kratzer's formula for the spectrum of hydrogen chloride) with

the measured wave-lengths. On the other hand, Ruark, Mohler, and Chenault attribute the fine structure of the lines to "transitions between components of complex spectral levels" (NATURE, Oct 18, 1924) They are satisfied that in the great majority of cases it can be proved that fine structures are not due to isotopy.

There are two conditions which must be satisfied by lines arising from isotopes (1) the intensities of the several isotope lines in the radiation from a thin layer must be in the ratio of the concentrations of the respective isotopes, (2) the radiation from the end of a long column should be distinguished by the equalisation of the brightness of corresponding lines when the column is sufficiently long for the lines to be "saturated" We have directed attention to this point in a recent paper (Proc Roy Soc. 105, p 527, 1924)

The application of the first test is difficult, but the second is possible in some cases In the case of 5461 Å all the satellites approximately satisfy the second condition, with the exception of one, namely, — 024 Å In the long column radiation the satellite — 024 Å is the brightest line of the group, and all the others are so nearly of equal brightness among themselves that the distinction, based on difference of intensity, between "main line" and "satellite" is lost. It appears to us that if the components of this group are to be attributed to the isotopes of mercury, the line — 024 Å must be excluded from the list. It appears, however, from the note of Nagaoka and his co-workers that they include this line in the isotopic group of 11 satellites, which, together with the main line, make up the whole group of 12 constituting 5461 Å

In the case of the two yellow lines 5791 Å and 5769 Å, these authors state that the observed wave-lengths of the satellites of 5791 Å agree with the calculated wave-lengths, whereas there is no agreement in the case of 5769 Å We, however, find that the side components of 5769 Å can be reversed on a continuous background, and that in long column radiation they approach the main line in brightness, whereas in the case of 5790 Å, we have been able to reverse the main line only, and the ratio of emission to absorption is greater for the satellites than for the main line Thus the components of 5769 Å appear to satisfy the second condition we have mentioned above, while those of 5971 Å do not

Chemical Combination of Helium.

THE views of Franck on the existence of a metastable form of helium capable of forming chemical compounds have led me, at the suggestion of Sir Ernest Rutherford, to search for such compounds. The experiments carried out during the past year indicate the existence of helium compounds of a different type from the mercury helide described by J. J. Manley in NATURE of December 13, p. 861.

I have examined mixtures of helium with the vapours of mercury, iodine, sulphur, and phosphorus under the influence of electron bombardment and in the presence of surfaces cooled by liquid air I find the helium disappears almost completely at a rate much greater than that observed under the ordinary conditions in a discharge tube Solid substances, which I believe to be compounds of helium, were condensed on the cold surface together with an excess of the other element used.

Numerous experiments were carried out which showed that the effect was not due to mechanical occlusion or adsorption. In the absence of a cold surface, a slow and very slight disappearance occurred, and the helium could only be recovered by heating the apparatus to 300° C. Experiments showed that this absorption or mechanical occlusion of helium in condensed vapours was very slight.

The substances obtained have a vapour pressure of the order of 0·005 mm. of mercury at −185° C. On allowing them to warm up, they decompose very suddenly at definite temperatures, and the original amount of helium is recovered. In the cases of mercury and iodine, this temperature is approximately −70° C and for sulphur and phosphorus −125° C The only disappearance of helium above these temperatures was of the order to be expected from the experiments described in the preceding paragraph In appearance, the compounds of mercury and iodine are not like the pure elements, but at the temperature of decomposition the appearance changes to that of ordinary deposits In the case of phosphorus, when the reaction is allowed to proceed, the deposit is yellow, but, if no reaction occurs, red phosphorus is obtained as might be expected since the vapour passes over a hot filament

Preliminary determinations of the velocity of reaction have been carried out, and further work on this point is in progress, as well as experiments which it is hoped will determine the composition of the products E H BOOMER.

Double Rainbows.

WHEN the source of light is at a practically infinite distance, as in the case of the sun, the position of the bow is determined only by the positions of the source and of the observer's eye When, therefore, a bow is seen double, there must be two effective sources. The phenomenon described by Mr. Deodhar in NATURE of December 13, p. 860, cannot be explained as due to two parallel rain showers Moreover, his laboratory experiment with a source of light near to the observer would be likely to mislead him, for the conditions brought about by the near approach of the source are greatly and strangely modified (see NATURE, Vol. 105, May 27, 1920, p. 389).

Two bows of the same radius but about two centres, one above the other, have been observed by the writer, the lower cast by the sun and the upper by the image of the sun reflected in a surface of water In the case described by Mr Deodhar the sun was low and rising, and if the upper bow were due to a reflected image the two bows would gradually separate and not approach one another as he observed them to do

Mr. Deodhar does not state in his letter whether he looked round to observe the sun at the moment. Perhaps he would have seen a second source of light, such as a small patch of brilliantly illuminated cloud near to and approaching the sun Another explanation that may be suggested is the duplicating of the sun's image by mirage or some other form of abnormal atmospheric refraction. The low altitude of the sun would favour this latter explanation.

Historical Aspects of Malaria.[1]

By Dr ANDREW BALFOUR, C.B., C.M.G

MALARIA AS A DESTROYER.

DESPITE all the knowledge gained by able and devoted men, despite the application of that knowledge in certain places, despite heavy expenditure, malaria remains one of the great killing and crippling diseases of the world. Let us consider some of the ancient records and see what they have to tell us First of all, however, it seems fitting, in the centenary year of Byron's death, to recall the last lines from his "Destruction of Sennacherib"—

> And the might of the Gentile, unsmote by the sword,
> Hath melted like snow in the glance of the Lord

It is of interest to note that Genovese, an Italian author who recently wrote an informative paper on "La malaria castrense"—that is to say, malaria in camps and incidentally in armies—is inclined to attribute the destruction of the Assyrian host to malaria It is of course impossible to be certain, but Palestine, then as now, was an intensely malarious country, and it is conceivable that a severe outbreak of malaria decimated the Assyrian army. If so the poet unwittingly approached the truth when he wrote

> For the Angel of Death spread his wings on the blast—

though, as only the female mosquito attacks man, *her* wings would have been nearer the mark The rapidity with which the destruction was accomplished as recorded in the Book of Kings is against malaria, but we need not take too *literally* the single night in which it is said that a hundred fourscore and five thousand perished.

Although it is impossible to speak with certainty, there is little doubt that ancient Egypt was heavily plagued by malaria. We know that it was a country full of great marshes, the remains of some of which persist to the present day, and the following passage from Deuteronomy has been cited as evidence of the existence of paludism "The Lord shall smite thee with a consumption and with a fever and with an inflammation and *with an extreme burning* and with the sword and with blasting and with mildew; and they shall pursue thee until thou perish"

It is not, however, until we turn to ancient Greece that we obtain anything like a true picture of malaria and its ravages. In "Malaria and Greek History," which Mr. W. H. S. Jones, of Cambridge, inspired by Sir Ronald Ross, wrote and published in 1909, it is claimed that malaria was the cause of Grecian decadence. Mr. Jones speaks of the malaria blight which fell upon many fertile districts of Greece about the fifth century B.C. He quotes the Wasps of Aristophanes to show that malaria, the "nightmare" disease as it was called, had invaded Attica, and that fevers and agues throttled the sires and grandsires of the Athenian people. He cites the treatise of Hippocrates on Airs, Waters and Places as proof that the father of medicine was very familiar with the dire results of malaria cachexia, with that chronic malaria which even to-day is wellnigh as hard to cure as it is to endure. Those who drink the water of marshes, said Hippocrates, have large spleens, but thin faces and shoulders. Again, after referring to the lowering of the birth-rate, owing to the physical condition of the women and the shortening of the span of life, he describes in a famous passage the people who dwell in low meadowy and hot districts, where the winds and waters are warm, as neither tall nor well-built, but short, fleshy, dark-haired, dark-coloured and bilious They are neither courageous, nor of great powers of endurance. The stoutness to which reference is made is doubtless perplexing, for the malarial cachectic is usually emaciated, but it may imply that the sufferers were œdematous or in an unwholesome condition There can be no doubt that in 400 B.C. large tracts of Greece were in a miserable state owing to malaria, while 200 years later the assertions of Polybius as regards the rapid depopulation of the country owing partly to emigration, partly to a heavy mortality, point, in some measure, to its malign influence.

In the olden days marshes surrounded Athens The Stadium was a swamp, and armies fighting round the capital suffered enormous losses It is recorded by Polyænus that Clearchus the tyrant, with the view of getting rid of a number of riotous and disaffected citizens, conscripted them to invest a town "in the dog days"—that is to say, in the summer—and made them encamp in a marshy plain "ill-ventilated and full of marshy pools," while he and his mercenaries occupied the surrounding hills The effect was rapid and terrible, for the wretched men were wiped out by malaria It is true that Dr Cardamatis, of Athens, a well-known malariologist, does not agree with the conclusion reached by Mr Jones, for he thinks the English author has overlooked the remarkable reclamation works carried out by the ancient Greeks, notably by the Minyans on Lake Kopais He attributes the decay of the nation to other causes than malaria, but, be that as it may, the destructive agency of the mosquito-borne disease is well exemplified in ancient Greece, where towns were actually given names signifying "heavy sickness" Some of these names, such as Kounoupia, Konopina, and Kounopitsa, exist to-day.

There are some who would attribute the decline and fall of Rome to the evil influence of malaria, and certainly in olden days the environs of the imperial city were described by classic authors, such as Cicero and Livy, as "Pestilentia" Tacitus states that Gallic and Germanic troops suffered severely by camping in the insalubrious neighbourhood of the Vatican, where the lands were covered with stagnant water and the air was unwholesome. Even at the present day a suburb of Rome is called "The Vale of Hell," and three-quarters of its inhabitants are saturated with malaria.

Genovese, already quoted, refers again and again to the havoc wrought by malaria amongst armed hosts. Many large Carthaginian armies faded "like mists before the wind" because of it, and the losses amongst the Roman armies in the wars against Hannibal must have been incalculable.

It is Banister the American, however, who brings things nearer home, for he declares that Brennus would undoubtedly have taken the Capitol at Rome had he

[1] From a discourse delivered at the Royal Institution on Friday, May 23.

not, in A.D. 208, lost in "Caledonia stern and wild" 50,000 out of 80,000 men from malaria.

So much for Europe long ago. A single example may be culled from the tropics, from the fate which overtook the people who built the lost cities of Ceylon, those wonderful ruins in its north central areas. Lucius Nicholl, of Colombo, believes, with some reason, that their ruin was occasioned by malaria. He points out that the ancient cities really owed their existence to the field labourers, who, by constructing tanks and by rice cultivation, made the country prosperous and self-supporting. It is reasonable to assume that the stress of devitalising diseases would fall upon them, and as the climate and the rainfall have not altered, there is every probability that malaria was imported from India with dire results

However interesting and suggestive these records and experiences from ancient times may be, they scarcely appeal so forcibly as those from later periods Take the extermination in the Roman Campagna in 1167 of the finest army ever commanded by Frederick Barbarossa. So rapid and awful was the destruction that the writers of the time have represented the disease as a "black cloud which covered all the valley near the Monte Mario, where the army was situated, and poisoned the air." A heavy rain had fallen in August and converted the place into a boundless swamp; then followed an enervating spell of hot weather, and an irresistible invasion of the wretched troops by fever. "Obscure soldiers, nobles and illustrious prelates laid down their lives there," says Genovese. The flower of a nation was exterminated, while in the same outbreak Rome lost some 20,000 inhabitants. Throughout the Middle Ages there were many deadly epidemics of the disease, like that of 1557–58 in England.

Let us fare to the tropics once again, and see how malaria wrecked high hopes and a well-found expedition when the ill-fated Scottish Darien scheme came to nought The settlers landed on a pestiferous spot of land in 1698 and speedily came to grief, mainly, if not wholly, by reason of disease There can be little doubt that malaria was the chief malady which overcame them, though yellow fever may possibly have been operative At any rate, the "Memoirs" of the Rev Francis Borland, who was one of the chaplains to the second portion of the expedition, leave one in no doubt that mosquito-borne fevers wrecked the enterprise. Two hundred years later a similar want of skill, due chiefly to lack of knowledge, occasioned, not far from Darien, a similar melancholy tragedy when the French failed in their great endeavour at Panama. It must be remembered that, though yellow fever proved their main adversary, malaria wrought much havoc in their ranks. It was left to the Americans, the heirs to learning gained partly by others, partly by themselves, to triumph over malign local conditions.

I have spoken of camps and armies, but navies have also felt the weight of malaria; the British Navy has suffered from it time and again. Perhaps the most dolorous account of its ravages is to be found in the records of the forgotten Batavian endemic, as it was called, which occurred in June 1800, when we were fighting the Dutch in Java. The ships concerned were the *Centurion* and the *Daedalus*—historic names. Seamen, marines, and soldiers alike suffered. The place of tragedy was the small island of Edam, nine miles offshore from the low swampy grounds of Batavia, and the remarks of Shields, the naval surgeon who is the chronicler of the disaster, are highly suggestive. He speaks first of Onrust, a small island only three miles from the main, well cleared of trees, underwood and jungle, nearly flat and free from swamps and marshes. Speaking of the sick brought here from the ships blockading Batavia, he says:

"From the fœtid exhalations, which were conveyed by the land winds from the neighbourhood of Batavia, the sick were easily secured, by closing certain apertures in their apartments, till the sun dispersed the vapours in the morning; after which there did not appear to be any danger from the miasmata disengaged during the day Edam, on the other hand, though farther out of the reach of Batavian exhalations, is covered with trees, long grass and jungle, having a part of the island itself in a stagnant, marshy state. The buildings here were indifferent, and only one long ward could be found for the sick and convalescents, in consequence of which the latter class of patients experienced all those dire effects produced by the depressing passions, forever nurtured by the melancholy scenes of death, which this fatal spot too constantly presented to their view! Thus, in running from a doubtful danger, they precipitated themselves on certain destruction. In leaving Onrust (a cleared space) to avoid the effluvium of Batavia, weakened and diluted by a three miles passage from its source, they settled on the jungly and marshy island of Edam, where pestilent miasmata, in a concentrated form, issued from every foot of ground around them! The fatal effects which followed were predicted by an intelligent surgeon on the spot, but his suggestions were disregarded or overruled, *distance* from the main being held paramount to all other considerations."

I might trace the deadliness of malaria from the Walcheren expedition, which it ruined, to the Crimea, where it played havoc, and on to Macedonia where it, more than any other single factor, rendered the Allied Forces in the War comparatively impotent I might tell you of great epidemics in India, of its strangling hold on the West Coast of Africa, of how the Indians in Mexico suffer and die from it; of the appalling conditions at present existing in Southern Russia; but I prefer to take one great classical example of its powers for evil within recent times—its invasion of Mauritius. It is unnecessary to consider the rights or wrongs of the story generally believed—to wit, that in the late 'sixties of last century, African malaria-carrying mosquitoes were introduced from a sailing ship, multiplied exceedingly, found infected blood already present in the bodies of Indians from India or Creoles from Africa, and commenced spreading the parasite, and incidentally the disease. I would rather give one or two passages from a book on Mauritius by Nicholas Pike, who was American Consul at Port Louis in 1867–1868, and was an eye-witness of the scenes.

"Those who inhabited Port Louis," he says, "during the terrible mortality in 1867 and 1868 will never forget the sad spectacles the city presented daily. Fever! Fever! was the only word on every lip—the only thought in every heart. Mourning and desolation everywhere. Scarcely a person visible that did not wear the garb of woe. Song and laughter had ceased.

"Port Louis was once remarkable for the number

of pianos heard in every street in an evening, from the Erard's grand and semi-grand to the humblest cottage instrument.

"At this time it was literally 'The daughters of music were brought low and the voice of mourning was heard in the streets.' Funeral trains were met at every corner. Relays of men were kept busy night and day digging the graves."

I have seen these graves, mute witnesses to the severity of the outbreak, to the dire results of ignorance. For months an average of 200 people died per day in Port Louis, and scenes such as Pike describes were common.

Think of what all this means, and what the discovery of the malaria parasite, and of the method of infection by the mosquito, has meant, and how much more it would mean if only men and governments would act energetically and enthusiastically upon the knowledge gained. When Mauritius passed through its furnace of affliction, and 31,920 persons perished, Laveran was a student at Strasbourg and Ross a schoolboy at Ryde

We have dealt with malaria as a destroyer *en masse*, but before looking at the reverse side of the medal and noting how it has benefited mankind, let us see what it has done in the way of removing notable persons in the historical sense, some of whom at least were valuable assets either to the communities they served or to the world at large. Naturally enough it is difficult to obtain trustworthy records from the far past In those days the word fever covered, if not a multitude of sins, a great variety of febrile disorders, and it is only in a few cases that definite clinical evidence is forthcoming which enables us to say that so-and-so undoubtedly perished from malaria. Even in comparatively recent times accurate diagnosis was difficult, for malaria is a very protean disease, and cannot be definitely predicated without the use of the microscope Hence my examples are scanty and some are doubtful.

Alexander the Great conquered the world, but there is some reason to believe that malaria conquered him, aided by his excesses and his disregard of precautions. Vasco da Gama voyaged half round the globe, but he voyaged to another, and it is to be hoped a better, land at the bidding of the malarial plasmodium—at least so it has been said. Anyhow he died of fever at Cochin, and his fatal illness was probably malarial in origin. "The wisest fool in Christendom" was undoubtedly killed by malaria. He died of ague at Theobalds. One of his predecessor's stoutest, but not too reputable servants, the bold Sir John Hawkins, had his end hastened by, if indeed it was not actually due to, the same disorder. Oliver Cromwell also, who died of ague at Whitehall, yielded his life to the insidious attack of the malarial parasite. Whether Byron was a victim of the disease when he died in his beloved Greece is a moot point. Sir Ronald Ross is inclined to think malaria was not guilty in this instance.

Careful research might add other names to this brief list. One would expect that of the great explorers in the tropics some were wiped out by malaria, but I have not been able to find indubitable evidence in the case of the greatest of them.

Malaria as a Benefactor.

Until very recently it would not have been possible to adduce evidence showing any *direct* benefit to man from the disease malaria, but a surprising development took place a few years ago when Prof. Wagner-Jauregg, of Vienna, began to treat cases of general paralysis of the insane—the dreaded G P.I —by introducing into the blood of patients the organism causing malaria, thereby producing in these patients attacks of malarial fever He had noticed, as had others, the beneficial effects of febrile attacks in cases of general paralysis, and conceived the idea of inducing high temperature repeated at short intervals It occurred to him that this is what the malaria parasite accomplishes in its victims, and that it might be used as a curative agent. Although patients were treated on these lines so early as 1917, nothing was published on the subject until 1920, but the remarkable results obtained in certain instances, and the fact that, in most cases, distinct benefit resulted, led to extensive trials of the new treatment on the Continent, and later to its employment in Great Britain.

Ere now one malady has been used to combat another, but never before has a serious disease been utilised in therapeutics which, once its good work is accomplished, can be effectively and speedily controlled. This is possible in the case of malaria, thanks to quinine, which, so far as its introduction into Europe is concerned, we owe to a woman, the Countess of Chinchon. We are able also to select one of the three forms of malaria which is the least dangerous, but naturally care must be taken that this use of the malaria parasite as a drug does not result in its dissemination by mosquitoes from those treated by it In Great Britain there is little danger of such an accident, but in Germany serious attention has been directed to it.

The method, promising though it be, is still in its infancy It is possible that it may be applicable to other diseases of the central nervous system, at least those due like G.P I to a specific spirochæte, but great care must be exercised, and this new therapy should be in the hands of experts familiar with the malarial plasmodium, and able also to gauge its effects. Those effects, it may be said, are not exercised on the other parasite, the spirochæte, nor does the high temperature affect this invader The action appears to be on the damaged tissues of the brain itself; but the precise mechanism is still obscure. If, however, malaria proves itself able to cope with locomotor ataxia, with disseminated sclerosis, and with paralysis agitans, then indeed it will be hailed as a benefactor, and be considered as having in some small degree made amends for its past atrocities.

Indirectly malaria has undoubtedly aided the human race. Mr. Jones ingeniously argues that it was responsible for the increased respect shown for women in the later days of ancient Greece, and cites the New Comedy (320–250 B.C.) as proof thereof. He considers that the value of women as nurses was made apparent by it, and that, as the wife was usually the nurse, endemic malaria vastly increased her duties and importance

The chief indirect beneficial action of malaria is to be found, however, in the way it has stimulated men to thought and action. From the earliest days mankind was forced to exercise ingenuity in protecting themselves from fever. Egyptian and Cretan fishermen slept under fishing-nets folded again and again until their meshes were small. They believed they were

excluding miasmata, but they were really keeping mosquitoes at bay. Yet so little is history regarded, perhaps because Herodotus wrote of this habit of Egyptian fishermen as a mere curiosity, that we find Prof. Traill in 1837 stating that the proposal to defend the body against marsh miasma by the interposition of gauze nets was first made by Rigaud de l'Isle in 1817, and recording that Brocchi had taken up the same idea, and averred that he had successfully employed it against malaria

Malaria inclined men from very early days to attribute the infection of fevers to mosquitoes or other biting insects Susiuta, an Indian physician who probably flourished in the fifth century B.C., taught this truth, and there is a picture of him expounding it to an Eastern potentate

Varro and Columella at the time of the Christian era associated mosquitoes with insects bred in marshes; but perhaps the most remarkable announcement was that of Lancisi, who, in 1717, stated that marshes were the cause of the fever owing to the transformation of minute worms into "stridulous culices," and that the poisoned animals kill, not by the wounds which they inflict, but by infusing a poisoned liquid through the wounds The Abbé de Fortis, writing of his "Voyage in Dalmatia" in 1774, refers to his meeting with an ecclesiastic who suspected that fevers were due to insects, the infection being derived from corpses or poisonous plants, and who thought that miasmas might be conveyed in this manner The conjecture, says the Abbé, is at least ingenious

So it went on with such protagonists as Nott the American, Beauperthuy the famous French Creole, Finlay of Havana, and King, the soundest of them all, reasoning and arguing in favour of the hypothesis and none paying much attention to them Yet malaria had taught benighted barbarians the lesson and they had accepted it Richard Burton in his "First Footsteps in East Africa," published in 1856, states that the people of Zayla in Somaliland believed that mosquito bites occasion deadly fevers, and says that the superstition (save the mark!) probably arose from the fact that mosquitoes and fevers became formidable about the same time

But malaria led also to closer and more scientific reasoning The ancestors of the malaria parasite were probably coccidia, tiny protozoa inhabiting the cells lining the wall of the intestine Some of these, naturally enough perhaps, got a little discontented with their surroundings, changed their habit of life, and eventually found a more congenial habitat in the red blood corpuscles Now Richard Pfeiffer, a trained observer, had been studying the coccidia of rabbits in 1889–90. He noticed that these parasites not only multiplied within their host, the rabbit, but, in a special resistant form, provided for their transference to another rabbit once they had got outside the body of their original host He recognised that the multiplication of the coccidia in the epithelial cells of rabbits and that of the malaria parasite in the red blood cells of man was a very similar destructive process, and thought that possibly the malaria parasite, like the coccidium, might have two cycles of development. If so it would have to get outside man's body. Provided it did not produce any resistant form to enable it to withstand the dangers it would encounter in the wide, wide world, say in soil or water (and such a form was unknown), he considered that it might make use of some insect in which, sheltered and comfortable, it could undergo the second, or as it is called exogenous, cycle of its development. It could then, as Koch had suggested to him, get back to man through the bite of some blood-sucking insect

This, as events have shown, was a prophetic utterance, but it was linked up with the earlier work of the great Sir Patrick Manson, who, long before, working in Amoy, far from books and skilled help, had proved that a mosquito served as the intermediate host of a human blood parasite, that tiny filarial worm, to the presence of which in the human body the disease elephantiasis is attributable He showed that the mosquito was a necessary link for the fulfilment of the life-cycle of the bloodworm This was a new conception in pathology of which both Koch and Pfeiffer were aware. Still this does not detract from the merit of Pfeiffer's carefully reasoned hypothesis. Neither he nor Koch, however, followed up the matter The solution of the problem was left to Ross, who, at Manson's instigation, took up the work in India, and after manifold trials and tribulations emerged victorious Certain Italian observers also contributed notably to our knowledge, and Ross himself, not content with mere scientific work, at once turned it to practical account.

Malaria, then, benefited man by stimulating him to undertake work for its own destruction, surely rather an altruistic action, and not unlike that of the medical profession itself. This stimulation has had other and far-reaching results, for, more or less as a direct outcome of the discoveries regarding malaria transmission and prevention, attention was directed to all kinds of protozoal and allied diseases. The American work on yellow fever was, in fact, the sequel to the researches of Ross, and an immense stimulus was given to the scientific study of tropical medicine and hygiene. One of the latest developments has been the application of electricity for the purpose of destroying mosquito larvæ and pupæ. Montellano, of Argentina, introduced the method of electrocution which is now being given an extensive trial.

Not only did malaria excite inquiry and interest, but education of the public was also found needful, and propaganda were launched broadcast. Man's ingenuity was stimulated afresh, for it was by no means easy to explain to lay audiences the intricate life-history of the malaria parasite; and further, his enthusiasm was aroused in an endeavour to present the problems of preventive work in an attractive and effective manner. Here it is that the Americans have forged ahead. Malaria is a very serious problem throughout the Southern United States, and indeed has been the reason why some of them have, until lately, been backward and depressed. The Americans are a practical people, and moreover are easily fired by that idealism which, if well regulated, so often spells success. Hence they have spared neither time nor money in combating malaria and bringing before the public by cinematographic films and other educational means the mysteries of the life-cycle of one of man's greatest foes, the measures taken to defeat it, and the results of a campaign well and truly waged.

Fuel Oil Resources of the Future.

By H. B. MILNER.

PUBLIC attention has once again been directed to the vital question of the world's resources of petroleum, in a paper read before the Institution of Petroleum Technologists by Prof. A. W. Nash and Mr. H. G. Shatwell on December 2, and further by a column having reference to that communication in the *Times* of December 3. The object of the paper is to allay uneasiness existing in the minds of many with regard to the adequacy of future oil resources

The argument requires that before justifiable fears are entertained we must be satisfied that all free petroleum in the earth has been located, that the problem of the origin of petroleum has been solved, and that "oilfields can be discovered and not simply located as a result of surface workings by local inhabitants." Alternative to natural mineral oil are "the abundant stores of bituminous material from which oil can be obtained by destructive distillation," these being oil shales, cannel coals, torbanites, lignites, peat, and coal.

With regard to the first point, it is maintained that outside America the search for oil has not been carried on diligently, and the implication is that, following precedent in the history of the American oil industry, more fields should be developed in other countries Then, the problem of the origin of petroleum not having been solved to general satisfaction, it is argued that it is impossible to state definitely that oil is not in process of formation at the present time. The third point is obscure both in definition and in amplification, though it is implied that improved technique is necessary in the initial stages of oil exploration The arguments in favour of the development of alternative fuel resources are not new, though great stress is laid on the commercial possibilities of "bergimisation" of coal and oil as a promising method of obtaining a substitute for natural petroleum.

It is difficult, despite the good case made out by the authors for peace of mind in connexion with future oil supply, to share fully their optimism, because while some agreement may be accorded with the facts they adduce in support of their opinions, their interpretation of the position and the conclusions they reach, since they are based on no new data, are open to question as much from economic as from technical points of view.

Misapprehension concerning the future of oil-fuel supplies was first of all felt and voiced, not by an irresponsible section of the community, but by experts both in the United States and in Europe, who realised the true drift of events. Far-sighted people, from an examination of the position from every angle—national, technical, economic—gradually came to see that if production did not keep pace with an ever-growing consumption, a most serious position would arise, probably within the course of two decades or so. Uneasiness spread, therefore, despite insistent press contradictions, instigated by interested persons, who did not hesitate to write up glowing accounts of a contemporary "oil age," and to quote misleading statistics to prove their optimistic contentions. Thus the industry and the public were entitled to an unbiassed knowledge of the facts, and also to considered and authoritative judgment on the position, either as a clear warning to be prepared for the worst, or as a vindication of the light-hearted optimism expressed in some quarters. The authors have therefore done well in bringing the matter once more to the front, even though we cannot agree with the reasons they consider sufficient to disarm fear for the future.

First, it is, we agree, reasonable to believe that all available petroleum has not yet been located; it would indeed be a poor outlook if this were so. But it is a question of magnitude of resources to be tapped, not merely the discovery of several comparatively small oil-pools. We have to ask ourselves whether, from broad geological knowledge of the world, there exist accessible regions outside the United States, where geological conditions are likely to favour the preservation of oil deposits on the vast scale which has made the industry in that country, and latterly in the world, what it is? Can we point to a second Pennsylvanian, Mid-Continent, or Californian region anywhere with any degree of scientific possibility? It is difficult to do so. It is, of course, possible to predict many localities likely to yield a future oil supply, on a par with, say, Persia, or Sarawak, at the present time, but it is not easy to visualise the existence of oil-pools the collective exploitation of which will determine an ultimate supply on the scale at present requisite, or likely to be demanded in the near future, if and when the United States with Mexico cease to yield 80 per cent. of the world's total output

Secondly, we may agree with the authors that the mode of origin of petroleum still remains debatable, despite more than thirty years of philosophy, but even if the problem were solved to universal satisfaction to-morrow, would the knowledge lead us to the location of deposits at present forming, and would such deposits be likely to have immediate economic value even if they were found? Whatever theory be advanced to account for the origin and accumulation of petroleum, the geological time-factor seems to be an inevitable influence in the mechanism, and yet we are asked to contemplate the prospect of contemporary petroleum, ripe for use, if not just at the moment, at least within the next few decades! An accepted solution of the genesis of petroleum is desirable for many reasons—mainly scientific—but the immediate economic significance of such a solution if arrived at, as indicative of a new line of field-investigation, is difficult to follow.

Thirdly, the authors suggest that mere geological examination of potential oil-bearing territory is insufficient, and should be accompanied at the outset by a drilling staff "to drill for geological information and not for oil." Where is the philanthropic company which can be persuaded to finance such a proposition? Further, the platitude is expressed that the science of geology of petroleum is an inexact one; since geology itself cannot be classed as an exact science, obviously a particular application must, *a priori*, be inexact But is it a whit more precise, as is implied, to encourage wholesale "wild-catting" of a kind which, while admittedly advisable from the purely technical aspect of field-geology, might only result in more failures to find oil, certainly in a heavier initial expenditure which the

average company director would never agree to incur, not even in these enlightened days of intelligent directorates? If the geologist is to be of any use at all in locating oil deposits, his work must precede exploratory drilling, for economic, if for no other reasons.

The authors also review the existing position of oil supply and mention more particularly possibilities in Persia. In this connexion, while sharing their opinion, we may be allowed the remark that even if Persia doubles her production in the next year or two, it would only represent 5 per cent. of the world's output at the present rate. They also stress the potentialities of the Canadian Athabasca tar-sands, a proper utilisation of only 25 per cent. of which would, they say, remove apprehension regarding the future. We refer them to the recent report by S. C. Ells (Bituminous Sands of Northern Alberta, 1924), in which he states (in reference to tar-springs) that "in no instances are they themselves of commercial value as a source of bitumen. They have, at times, been regarded erroneously as a definite indication of the presence of petroleum pools." Later, summarising several processes devised for producing oil from these tar-sands, he says, "The results of this work are as yet inconclusive."

A further "off-set" to shortage of supply is the possibility of mining for recoverable oil from abandoned oil-fields by shafts and galleries, as at Pechelbronn; this principle, apart from the human factors involved, may be economic with shallow sands in some cases, but what of oil-sands lying between 3000 and 5000 feet below the surface. would the method be practicable, and does it therefore help the solution of the difficulty?

Lastly, we reach the question of alternative fuel resources, and here, while the authors are to be congratulated on the way they have marshalled the possibilities of shales and coals, they should in fairness have laid more stress on the technical difficulties at present in the way of utilising these resources on a satisfactory commercial scale. The world's known resources of oil-shale are now generally appreciated, but the estimates given by Alderson and others as to the amount of oil recoverable from them are quite fictitious until suitable retorts and processes are devised for treating them economically, while apart from any other difficulty, desulphurisation of shale-oil and high refining losses still remain in many cases thorny impediments to development, as in Great Britain.

The difficulties concerned with coal and allied carbonaceous material as a source of oil are similarly those concerned with large-scale treatment for commercial supply. Low temperature carbonisation is, from the economic point of view, a process which has yet to be extended under modern conditions of fuel supply and efficiency. Even if successful, oil thus obtained, as the authors admit, can never adequately replace petroleum products. The "berginisation" of coal and oil, regarded by the authors as being of great promise, is in an experimental stage, and much ground has yet to be covered before the application is a practicable one from a commercial point of view. This process consists in heating in the presence of hydrogen a mixture of powdered coal containing less than 85 per cent. of carbon, with mineral oil or tar oil at high pressure (100 atm.) and temperature (400°-430° C.), when a liquid product closely resembling petroleum results. It may be pointed out that unless the liquid product is capable on refinement of yielding a range of products which will take the place of petrol, kerosene, lubricating oil and fuel oil, the process loses at once in value as a means of producing artificial fuels. At present we have little trustworthy data concerning either the refinement or the quality of such "berginised" oil.

Thus the whole question remains in an unsatisfactory position, and it cannot be said that a critical examination of the authors' thesis advances things much further. We endorse, as every student of science will do, their insistence on the need for research, not only for posterity, but also for our own sakes. Conservation of petroleum resources will automatically come, whether we urge it or not, since for strategic reasons alone the United States will ultimately have to limit its exports of oil, and that, too, within the next two decades, if further large supplies are not forthcoming. Once the United States decides on that policy, Europe and all other countries dependent on it for the larger proportion of their oil-fuel requirements will have to face the inevitable, and either economise in the use of petrol and petroleum products, or provide some alternative, but probably in the long run, far less convenient fuels and lubricants.

Hence the keynote to the situation may be summed up in the word economy. The present heavy-handed use of petroleum results from a general impression that there is plenty more where the present supply comes from, an extravagant idea inculcated by the same policy responsible for recent deplorable overproduction and wasteful consumption. If the industry, by adopting in the future the practice of husbanding existing resources and by straining every scientific nerve to a higher technique in production, refinement and utilisation of oil-fuel, thus sets the example to the public, the public itself will be educated: Decline in cumulative production in such circumstances will be slow; the full and beneficial effect of each new discovery of an oil-pool, however small, will also have time to operate, and the gaining of time in one way means that the chances of developing new schemes of alternative fuels, as outlined by the authors, are more likely to meet with success, at all events as commercial propositions.

Some people hold that we should enjoy the gift bestowed on our own generation, the privilege of living in an "oil age," and leave posterity to take care of itself. This is neither a credit to contemporary knowledge, nor is it in keeping with the best traditions of scientific progress. We owe it to ourselves to face the situation as repeatedly exposed by David White, Pogue, and others qualified to judge, and whatever position may ultimately be created by a shortage of natural petroleum, we have to see that we are not unprepared to meet the contingency either through lack of foresight or of initiative in perfecting substitutes. But we have also to realise that the prospect of supplanting petroleum by alternative, artificial fuels is confined largely to the realm of experimental possibilities; merely to define the possibilities is not necessarily to remove the qualms which still exist in the minds of not a small section of workers in the oil industry.

Current Topics and Events.

IT is a biological commonplace that every species of animal (man included) tends to increase in numbers if left free to propagate without restraint. This restraint is, however, always forthcoming when the population reaches a certain degree of saturation, and in the case of the human race it has in the past taken three forms, namely, war, famine, and pestilence. During the fourteenth century there were seven famines in England, in which the people died like flies, and towards the close of the century the Black Death wiped out three-quarters of the population. We are familiar with the ravages of the Great Plague in London in 1666, during which 100,000 people died, but few realise that in the preceding century there were two similar visitations, and in the earlier one, which occurred in Elizabeth's reign, 65,000 people died. The Queen and Court fled to Windsor, and the Queen had a gallows erected in the market-place, and gave orders that every Londoner who appeared in the town should be hanged!

WITH the development of our social sense, which is the real measure of our advance in civilisation, the suffering and sorrow involved in these calamities have become abhorrent to us, and a certain proportion of our population, chiefly the better educated members of it, have learned so to limit their families that they are able to give to each child its proper share of care, food, and affection. But the greater part of the population, including most of the manual workers, are without this knowledge; and amongst them the lowest, poorest paid, and least skilled are the most prolific. The Walworth Women's Welfare Centre (153A East Street, Walworth, S.E.), the annual report of which has recently been received, was established with the object of teaching the poorer women harmless means of preventing conception, so that the births may be properly spaced and the children given a chance of healthy development. A distinguished Dutch medical man, Dr. Jansen, in a book entitled "Feebleness of Growth," has given reason to believe that in successive children produced by rapidly succeeding pregnancies, there is a progressive physical degeneration manifesting itself in stunted growth and deformities of various kinds. It would seem that birth-control should ultimately replace natural selection as a limiting factor in human affairs: but if it is confined as at present to the best elements of the population, it must cause the deterioration of the quality of the race. The aim of the Walworth centre and of the newly established centre in North Kensington is to spread the knowledge amongst those who need it most.

THOUGH to-day some 2,000,000 tons of shipping are propelled by internal combustion engines of the Diesel type, a new chapter in the history of the motor ship may be said to have been opened with the recent trials of the M.S. *Oorangi* built by the Fairfield Shipbuilding and Engineering Company of Govan for the Union Steamship Company of New Zealand. The *Oorangi* (the name is the Maori for Mount Cook) is the first large and fast passenger vessel to be fitted with Diesel engines. The ship is 23,000 tons displacement, 600 feet long by 72 feet beam, and will carry about 1300 passengers and crew and a considerable amount of cargo. It is designed for the long run from Vancouver to New Zealand and Australia, on which it is expected that an average speed of 17½ knots will be maintained. The main interest lies in the vessel's machinery. There are many types of Diesel engines being produced to-day, but the engines of the *Oorangi* are of the Sulzer type, two-stroke, single-acting, as developed by the famous Swiss firm of Sulzer Brothers of Winterthur. There are four sets of main engines driving four shafts, each set having six cylinders 27½ inches diameter, 39 inches stroke, the whole 24 cylinders developing some 15,000 B.H.P., equivalent to 19,750 I.H.P. The air compressors for supplying the air, at 1000 lb. pressure, for injecting the fuel are worked off the main engines, while the low-pressure air supply for scavenging is obtained from three turbo-blowers driven by electro motors. There are also two electro motor-driven high-pressure air compressors for supplying the starting air when manœuvring in and out of port, while the electric power installation for the ship consists of four 350 kw. generators driven by Sulzer-Diesel engines of 420 B.H.P. Some of the auxiliaries in the ship, such as the refrigerators and winches, are driven by steam supplied from two ordinary marine boilers burning oil. The ship carries about 3000 tons of oil fuel, which is sufficient for the round voyage between Vancouver and Sydney. As pointed out by Engineer-Admiral Sir George Goodwin in his Hawksley Lecture to the Institution of Mechanical Engineers on November 7, there are many considerations to be taken into account when deciding upon the type of machinery for any particular ship, and the performances of the *Oorangi* at sea will be followed with great interest.

THE value of an international language for promoting amity among nations, and its obvious advantages for use in international trade, have been much emphasised by those who are convinced of the practicability of such a project, but its presumptive value to men of science has, perhaps, not yet received due attention. The work of a large number of scientific and technical societies is severely handicapped by the greatly increased costs of printing and publication, and the adoption of a single language for communicating abstracts from scientific literature, as well as for papers and treatises of exceptional importance, would undoubtedly effect economies in money and effort. In a recent issue of the Proceedings of the American Philosophical Society (vol. lxiii., No. 1), Prof. R. G. Kent, of the University of Pennsylvania, makes a thoughtful contribution to this subject. After referring to the use of Latin by scientific investigators from about A.D. 1500 until 1775, and to the recrudescence of national feeling and national languages since the War, the author declares that the language burden has now become too great

even for the professional philologist and *littérateur*. He discusses the merits of the chief languages that have been suggested for international use, and comes to the conclusion that Latin is best for scientific purposes. Latin has a vocabulary that is essentially international, and a technical terminology which is already very wide and capable of easy and indefinite extension. Although ease of acquirement and brevity are valuable characteristics of an international language, a recognised and unquestioned standard of meaning is even more important. Latin has an objective standard of word-meaning, and by reason of its terminations, word-order, and moderate use of auxiliaries, it allows of complete precision in indicating the relations of words to one another, it is reasonably phonetic; it is still used for constructing new words required in science; of all non-native languages, it is most studied in European and American schools, and its use would not inflame international jealousy. Prof. Kent advocates the use of a simple Latin, *i.e.* one with short sentences and few clauses, together with a slightly increased number of prepositions. Thus modified, he thinks that Latin would stand supreme as a means of conveying scientific thought to an international public.

At the last meeting of the Newcomen Society held on December 17, another valuable contribution was made to the early history of mechanical engineering by Mr Forward in a paper on "The Early History of the Cylinder Boring Machine." The lathe, the planing machine, and the boring machine have all been developed into very powerful and accurate machines, but some of their principal features can be traced back to the pioneering machines. It was the steam engines of Newcomen, Smeaton and Watt which created the demand for cylinder-boring machines, and one of the first is that described by Smeaton as seen at the Carron Ironworks, but it was as imperfect as Watt's "Beelzebub" itself. It was the well-known ironmaster John Wilkinson who first used a long stiff cylindrical bar fitted in bearings and provided with a cutter head of large size which could be traversed along the bar by means of a rack and pinions. It is possible the old boring bar at the Science Museum, South Kensington, was one of Wilkinson's earliest and was used at Bersham. Another improvement was the use of a screw instead of the rack, but it is not certain who made this important addition. Among the engineers of that day was Matthew Murray of Leeds, and it may have been due to him. In speaking of the making of the screws, Mr. Forward quotes an interesting passage from T. Gill's "Technological and Microscopical Repository" of 1830, showing how the lines for the screw were first produced on the bar, how a shallow screw thread was cut by hand, and how this shallow screw was used for completing the cutting.

A report by Mr Leslie Armstrong on recent results obtained by the joint committee of the British Association and the Royal Anthropological Institute for the exploration of caves in Derbyshire appeared in the *Times* of December 22. An undisturbed occupation site at Creswell Crags, opposite a cave, known as Mother Grundy's Parlour, at the eastern end of the ravine, has yielded rude implements of quartzite, more than 1500 flint flakes and implements, a number of bone tools, and numerous bones of pleistocene animals. More important, however, are examples of palæolithic art in the form of engraved bones, one a spirited drawing of a reindeer, another a part of a bison with the head, and a third fragment too small for identification. The only other undoubted example of palæolithic cave engraving from Britain is that of a horse's head from the Robin Hood Cave, also at Creswell, found by Sir W. Boyd Dawkins in 1876. The earliest implements—flakes and hand-axes made from quartzite pebbles of late Acheulean form—were associated with remains of cave lion, cave bear, and hyæna. They represent not only the earliest occupation of Creswell, but also the extreme northward extension of early palæolithic man in Britain. A considerable interval elapsed between this and the next occupation, which belongs to the Reindeer Period. In this stratum were flint tools of Upper Aurignacian type, the engraved fragments of bone, and tools manufactured from reindeer antler and bone. A hearth or fire-hole was scooped out in the basement bed and ringed with flat stones. Not only does the evidence from the cave earth here indicate continuous occupation from late Aurignacian to Azilio-Tardenoisian times, but it also supports the view which challenges the existence of true Magdalenian culture in Britain, and maintains that there was an independent development of culture here which was free from intrusive Magdalenian influence.

The December issue of *La Science Moderne* contains an article by M. Reverchon on "L'Evolution de l'Horlogerie." M. Reverchon points out that the mechanical clock was the gift of the middle ages, and its development belongs to the last six hundred years. One of the first clocks made was that constructed for the Cathedral of Beauvais, but the oldest clock still going is that in the Science Museum at Kensington. The fourteenth century saw many cathedrals supplied with clocks. All of these were fitted with the verge escapement—the first of all escapements—the inventor of which is unknown. "Nous sommes ainsi reduits à le saluer comme le soldat inconnu de la chronométrie." The verge escapement was the only one used for three and a half centuries, and even the pendulum clock presented by Huygens to the States General of Holland had it. A little later came the anchor escapement of Hooke or Clements, and then others by Graham, Le Roy, Lepaute, Mudge, and others. In his sketch, the author divides the history of the clock into three periods, the second of which opens with the work of Huygens, while the third, "the scientific period," began with the work of Edouard Phillips, who in 1861 published his essay "Mémoire sur le spiral réglant."

Marine meteorology is dealt with in the *Marine Observer* for December published by the Meteorological Office, Air Ministry; this completes Vol. I., which commenced with 1924. The publication emanates from the Marine Division; communications are contributed by the marine staff, and interesting

items are given by the voluntary marine observers, for whose benefit the work is primarily undertaken. "Wireless and Weather, an Aid to Navigation," has been made a special feature throughout the year, and the December number is of special interest to seamen, dealing with phenomena common to the Atlantic and Pacific Oceans. A quotation is given from "Physical Geography of the Sea and its Meteorology," written by Maury about sixty years ago, given apparently to show that over the open ocean there are no interfering causes as commonly exist over land. With our present knowledge of the weather, the North Atlantic with its cold Arctic current flowing southwards and the Gulf Stream flowing northwards, together with other interfering causes, it is not easy to admit that over the ocean "the agents which are at work are of a more uniform character" Synchronous weather charts are given, drawn at sea from wireless reports received, and these will prove very helpful to other observers wishing to obtain similar information It is only recently that it has been possible to draw weather charts at sea, of similar use and with somewhat equal accuracy to the synchronous charts drawn on shore at special weather bureaux A retrospect of the results given in the first volume and the interest in the work taken by seamen is said to justify the continuance of the publication Without doubt marine observers are regaining their pre-War interest in meteorology.

AT the twelfth annual meeting of the Indian Science Congress to be held at Benares under the auspices of the Benares Hindu University on January 12-17, His Highness the Maharajah of Benares will be the patron and Dr. M O Forster, Director of the Indian Institute of Science, Bangalore, will be the president. The Sections and their presidents are as follows.—*Agriculture*, R. S. Finlow, Director of Agriculture, Bengal, Dacca, *Physics and Mathematics*, Prof E. P. Metcalfe, Principal, Central College, Bangalore, *Chemistry*, Dr. J. C. Ghosh, University professor of chemistry, Dacca; *Zoology*, Dr Baini Prasad, Officiating Director, Zoological Survey of India, Calcutta; *Botany*, Prof. R S. Inamdar, University professor of botany, Benares Hindu University, *Geology*, Dr G E Pilgrim, Superintendent, Geological Survey of India, Calcutta; *Anthropology*, Prof P C. Mahalanobis, Presidency College, Calcutta, *Medical Research*, Lieut.-Col F. P Mackie, Director of the Bombay Bacteriological Laboratory, *Psychology*, Dr. N. N. Sen Gupta, professor of psychology, Calcutta University. Besides the usual sectional programme, general discussions have been arranged on the following topics. The physical and chemical aspects of valency; the true path of industrial development in India; the relation of insects to disease in man, animals and plants; the fauna and flora of Krusadai Island near Rameshwaran. Popular evening lectures will be delivered by Prof. A. J. Turner, on "Science and the Cotton Industry"; by Dr. S. N. Gore, on "Bacterial Flora of Drinking Water in India", and by Prof. P. Sampat Iyengar, on "The Growth of India." Lieut.-Col. F. P. Mackie will give a cinema demonstration on malaria and kindred subjects. A number of excursions and social functions are also being arranged in connexion with the Congress

SIR OLIVER LODGE has accepted the presidency of the Radio Society of Great Britain in succession to Dr W. H. Eccles, who has held the office for the past two years

WE much regret to record the death on December 26 of Dr G D. Liveing, F R S., president of St John's College, and formerly professor of chemistry in the University of Cambridge Dr Liveing, who reached the advanced age of ninety-seven years on December 21 last, was the victim of an accident some two months ago and he never recovered His early work was chiefly in the domain of spectroscopy, and he was awarded the Davy Medal of the Royal Society for his contributions to that subject so long ago as 1901

PROF E. GOURSAT, of the faculty of science of the University of Paris, and Prof L Bianchi, professor of analytical geometry in the University of Pisa, have been elected associates of the section of mathematical and physical science of the Académie royale de Belgique (Classe des Sciences), and the Lamarck Prize (Zoology) has been awarded to Prof E Chatton, professor of general biology in the University of Strasbourg

THE University of Sydney commemorated on October 23 last the centenary of the publication of Sadi Carnot's "Réflexions sur la puissance motrice du feu" Representatives of almost all the scientific and educational institutions of Australia were present at the commemoration Lectures on the bearing of Carnot's work on modern science and industry were delivered by Sir Henry Barraclough and Prof. O. U Vonwiller, and exhibitions and demonstrations of modern oil, gas, and steam engines and refrigerating machinery were given in the Engineering Laboratory of the University

IN conjunction with the Meteorological Office, Mr S Morris Bower, Langley Terrace, Huddersfield, purposes to continue, during this season (January 1-March 31), the annual record of winter thunderstorms in Great Britain hitherto made by Mr. C J P. Cave, of Petersfield (see NATURE, December 30, 1922, p 877). Reports from all parts of the country are desired, especially from Scotland, Ireland and the North of England.

THE last meeting of the Illuminating Engineering Society was held at the E L M A. Lighting Service Bureau—an interesting departure with the view of bringing practice and theory into line Visitors, including representatives of gas lighting interests, had an opportunity of witnessing demonstrations of the latest types of lighting units and examining critically methods of impressing the benefits of good lighting on the public. Some of the appliances shown illustrated aptly the application of scientific principles in the lighting industry, and there was one device, a new form of camera shown by Dr Rosenthal, that excited considerable interest. This compact form of

camera is expressly designed for taking photographs by artificial light and is provided with an exceptionally large aperture. It was stated that an exposure of two seconds was sufficient with illuminations not less than 5 foot-candles—a speed that would easily enable photographs of artificial lighting installations to be taken with figures in the foreground In the case of factories, this is likely to be a considerable advantage

KING EDWARD'S HOSPITAL FUND for London has arranged a series of evening popular science lectures, by distinguished scientific workers, during January, February, and March. The lectures are to be given at the Imperial College of Science and Technology, King's College, Birkbeck College, and various polytechnics spread over London, and the proceeds go to the Hospital Fund Sufficient guarantee of the interest of the lectures is given by the list of lecturers: Sir Sidney Harmer, Sir Richard Paget, Bart, Sir Robert Robertson, Profs Winifred Cullis, A O Rankine, S. Chapman, E W MacBride, C S Myers, G. Elliot Smith, E N da C Andrade, J S S Brame, F J Cheshire, and Leonard Hill, Mr. W E Garner, Mr. C R Darling, Capt P P Eckersley, and Major R. W Mayo. Tickets can be obtained from the secretary of the institution at which a lecture is to be held, or from the secretary of King Edward's Hospital Fund for London, 7 Walbrook, E C.4 (price 1s); serial tickets, available for any number of the lectures (price 4s), can also be obtained at the latter address. Admission is by ticket or payment at the entrance

"THE Abridged Scientific Publications from the Research Laboratory of the Eastman Kodak Company" is in future to be issued annually because of the increasing number of the publications that have to be dealt with The seventh volume that has just been received gives, in a slightly abridged form, the 22 papers that were printed during 1923 in various English, American, and French scientific journals. The full reference is given to the original source in each case, so that any one specially interested in any particular paper may refer to the full communication. The abridgments are classified under the headings of physical optics, photographic optics, inorganic, organic, physical and colloid, and analytical chemistry, photographic theory, and practical photography. They carry forward the work for which this Laboratory has become so well known.

THE Cambridge University Press announces for early publication "Scientific Papers," by the late S. B McLaren, dealing mainly with electrodynamics and natural radiation. The work has been prepared for publication by Profs. H. H Hassé, T H Havelock, J W. Nicholson, and Sir Joseph Larmor The same firm also announces "Plant Life on East Anglian Heaths," by Dr E. P. Farrow. The volume will contain an account of some observations, problems and experimental work relating to the ecology of the vegetation of the East Anglican heath district known as the "Breck Country"

"THE Scientists' Reference Book and Diary," published by Messrs. Jas. Woolley, Sons and Co., Ltd, 76 Deansgate, Manchester, is as attractive and handy a book as any scientific worker could desire. It includes useful information, constants, and conversion tables, relating to many branches of science, lists of universities and scientific institutions, mathematical tables, and much other matter, in addition to a diary for 1925 and several detachable pages of squared paper The price of the publication is 3s. 6d., and we can confidently recommend this twenty-seventh issue to all science teachers and students.

Our Astronomical Column.

A NEW COMET?—A telegram from the Copenhagen Astronomical Bureau announces the discovery of a nebulous object by Prof Wolf at Königstuhl Observatory on Dec $23^d\ 8^h\ 15{\cdot}7^m$ G.M.T Its R.A. was $4^h\ 8^m\ 19\ 47^s$, N. Decl $24°\ 31'\ 36''$ (referred to equinox of 1924 0), daily motion -28^{sec}, south 14′, magnitude 16·0

Two plates were exposed by Mr G Merton with the 30-inch reflector at Greenwich on Dec. 26, but up to the present, the object has not been located upon them It is clearly beyond the reach of ordinary instruments

VARIATION OF LATITUDE.—The *Japanese Journal of Astronomy and Geophysics*, Vol 2, No. 3, contains a discussion by H Kimura of the results obtained at the international latitude stations, Mizusawa, Carloforte, and Ukiah, in the last two years. The star-places and proper motions have been rediscussed; the amplitude of the combined wave during the period discussed is about 0 2″, that of the ε or Kimura term about 0 05″.

The author concludes that there is a 19-year term in the variation, and that the following sub-multiples of this period have sensible coefficients: $\frac{1}{18}$, $\frac{1}{19}$, $\frac{1}{14}$, $\frac{1}{13}$, $\frac{1}{18}$, $\frac{1}{18}$, $\frac{1}{11}$. The second and fifth have the largest coefficients. These are the well-known annual and 14-month terms. He further believes that terms found in earthquake analysis appear also in the polar motion, indicating a close connexion between the phenomena

CONVECTION CURRENTS IN THE ATMOSPHERES OF THE SUN AND STARS.—The Proceedings of the National Academy of Science, Washington, for September 1924 contains a paper by C. E. St. John and H. D. Babcock on this subject. They confirm previous conclusions that the pressure is a small fraction of an atmosphere, being 10^{-1} atm. at the photospheric level, 10^{-4} at 5000 km., and 10^{-18} at 14,000 km. The daily rotations at these heights are 13·84°, 14·44°, 15·4°, and the linear velocities 1·97, 2 06, 2 18 km./sec. The convection currents are downward 0·5 km./sec. at 14,000 km., downward 0 3 km./sec. at 1500 km., and upward 0·3 km./sec. near the photosphere. The authors have made a similar examination of the spectra of Sirius, Procyon, and Arcturus; they conclude that the difference of convection speed for high level minus low level increases with temperature, being 1·20 km./sec. for Sirius, type A, 0·67 for Procyon, type F, and 0·34 for Arcturus, type K. It may well amount to 4 km./sec. for type B, which would explain the well-known "K" term for these stars. The pressures in the atmospheres of Sirius, Procyon, and Arcturus are concluded to be of the same order as that in the sun; the largest value found is 0·4 atm.

Research Items.

HEREDITY IN FINGER PRINTS.—Attention was first directed to the indications of heredity in papillary ridges by Galton, upon whose investigations our knowledge of finger prints is based. His evidence on this point consisted of a statistical treatment of 150 fraternal couplets, an investigation of 17 sets of twins, and a comparison of children with their parents when both parents were like patterned. Galton himself pointed out that the number of his cases was too few to justify quantitative conclusions The question has been investigated further by later workers, of whom the most recent is Mlle. Kristine Bonnevie, of the University of Kristiania, who has had the finger prints of the Court of Justice of Kristiania placed at her disposal. This material covers 24,578 Norwegian criminals The result of an examination of these data is published in the *Journal of Genetics*, vol 15, pt 1. The statistical investigation follows Galton's results very closely, showing a percentage for all fingers :—whorls 25·65, radial loops 5·81, ulnar loops 61·14, and arches 7·4, the distribution being characteristic for all fingers. A comparison with material from other races showed the total numerical occurrence of each pattern type to be characteristic of each race investigated, while the distribution of each type upon the various fingers showed in all races the same characteristics as in the Norwegian material Among other conclusions of considerable importance, a number derived from data furnished by related individuals clearly suggest that finger patterns are hereditary Further, there is seen to be a causal connexion between the appearance of the patterns and the shape of each finger-ball

THE CULTURE OF THE NEWARS —The Newars form the most numerous group of the inhabitants of the Valley of Nepal proper, and afford an interesting example of the effect of a fusion of cultures—a point of view from which they have been studied by Mr. K. P Chattopadhyay in a communication in the Journal of the Asiatic Society of Bengal, N.S vol. xix pt. 10 They are divided into the Bauddhamārgis who worship Buddha, and the Sivamārgis who worship Siva, but since their conquest by the Gurkhas, who entered Nepal in 1768, the former have, under the encouragement of their conquerors, lost ground to the latter, who may be termed Hindus, and have an organisation similar to that of the Hindus of the plains, though of a simpler character The Bauddhamārgis are divided into three grades A peculiarity of the castes is that most have a religious duty to perform at the festivals, and are as much religious organisations as social Among the Hindu Newars, the only definite secular occupation followed by any caste except fighting, trade, and cultivation, is that of cowherds. All other occupations are followed by pure and mixed Bauddhas. It is clear that the employment of cattle was not known to the Newars in ancient times, and even now is comparatively rare. Before the knowledge of cattle was introduced to Nepal, a culture characterised by knowledge of metal, wood and stone working, as well as hoe cultivation of a peculiar type, existed, and must have come from elsewhere, being imposed on a country inhabited by rude and wild tribes. An analysis of religion, social organisation, and arts and crafts indicates that this early culture came from India, and not Tibet as has been suggested. This was followed by a later Brahmanic conquest or incursion with a culture not strikingly superior to that of Nepal, into which it was assimilated. It differed in type from that Brahmanic civilisation which affected the Gurkhas.

BRITISH FOSSIL ELEPHANTS.—In *La Nature* for November 15 (No. 2641), Dr. Georges Pontier gives an account of his researches on the British fossil elephants. He figures selected specimens attributed to *Elephas planifrons*, *E. meridionalis*, *E antiquus*, *E. priscus*, *E. trogomtherii* and two forms of *E primigenius* In a table at the end he sums up his views of the evolution of the group as exemplified by the British forms, and in these views he follows very closely those of Depèret and Mayet, whose paper published in *La Nature* for August 25, 1923 (No. 2577) has already been noticed in these columns (NATURE, September 15, 1923, p 405). While the view, which we owe to Depèret and Mayet, that the various species of elephants form separate lines, with little or no connexion with one another; that, for example, *E planifrons* gave rise to *E. meridionalis* and its mutations only, that *E antiquus* is separate from it and so on, is a view which is attractive and easy of comprehension, it is nevertheless not entirely borne out by a closer survey of all the material in the numerous large collections in Great Britain It takes no account of the many apparent intergradations of the pattern and other characters of the molar teeth which have led many other authors to the different conclusion that there is much interrelationship It places also too great a reliance on the supposed correctness of the sequence in time of the described mutations, some of which can be shown to occur in England in the same beds instead of appearing in subsequent strata The paper, however, forms an interesting and valuable contribution to a very perplexing problem.

NORTH AMERICAN MAMMALS —Mr. G S. Miller has a two-fold object in drawing up his List of North American Recent Mammals, 1923 (Bull U.S Nat. Mus., No 128). to direct attention to the richness of the United States National Museum collections, and to furnish a summary of the systematic results of the study of North American mammals to the end of the year 1923 The stupendous nature of Mr Miller's task may be gauged from the fact that the United States National Museum collections contain 106,000 skins, three-quarters of which have been brought together by the United States Biological Survey, to the work of which Mr Miller pays full tribute. The completeness of the collections may be judged when it is remembered that out of 2554 forms represented in North America, only 171, or less than 7 per cent, are absent from the national collections, while the number of types at the disposal of the author was 1435 Mr Miller has furnished under each species or sub-species a reference to the first publication of the name, or to the publication in which it was first admitted to the North American list, and he has correlated his nomenclature with previously published lists. Under each form the type locality is given with great exactitude, and the known range briefly indicated. Mr. Miller's paper will be an invaluable work of reference for all engaged in the study of mammalogy.

A PROBLEMATICAL ORGAN IN THE LAMPREY —Mr. G. R. de Beer (*Jour. Anat.*, vol lix pt. 1, pp 97-107, October 1924) has investigated the problematical organ in the olfactory capsule of Petromyzon first made known by W. B. Scott, and the subject of much speculation by subsequent workers. The organ is vesicular, the vesicles being closed, lined with ciliated glandular cells, containing fluid, and immersed in blood sinuses innervated by branches of the olfactory nerve. The diverticula from which the vesicles

arise in the larva contain secreted (excreted) matter, and the fluid in the adult vesicles is evacuated through the blood There is not sufficient evidence to indicate the homologies of the organ, but the author thinks the evidence not strong enough to warrant the suggestion that it is the homologue of Jacobsen's organ He inclines to the view that it is a gland, possibly endocrinal in nature, the secretion being carried away in the blood sinuses with which it is surrounded Experimental tests with extracts from the organ give negative pituitary reactions No similar organ was found in the allied genera Myxine or Bdellostoma

A DEVONIAN PLANT WITH ALGAL ORGANISATION AND TETRADS OF RESISTANT SPORES —This interesting conjunction of characters seems to be present in *Sporocarpon furcatum*, a fossil plant from the black shale of the Devonian strata of Ohio, first described by Sir William Dawson, who saw in these saccate, flattened pellicles, the compressed remains of the sporocarps of some unknown plant The late Dr R Kidston and Prof W H Lang now report, in the Transaction of the Roy Soc of Edinburgh, vol 53, pp 597-601, the finding of tetrads of spores in specimens of this plant The authors conclude that the mode of occurrence, general appearance, and structure of the specimens strongly suggest that they are the more persistent tips of some thallod Alga of the period The disposition of these spore tetrads might be paralleled among living Rhodophyceae, but the resistant nature of the thick wall of the spores and the presence of surface marking corresponding to the place of contact of the spores then become features of extraordinary interest, as they are not found in any known Alga

THE IMMUNITY OF APPLE STOCKS FROM WOOLLY APHIS —In the *Bulletin of Entomological Research* for November 1924 (vol xv pp 157-170), Mr L N Staniland attempts to explain this immunity in certain apple stocks It is well known that the woolly aphis induces gall formation on its host plant, and Mr. Staniland remarks that the cambium is affected, almost certainly by the salivary secretion of the insect, in such a way that each of its cells divides more rapidly than normally, thus producing the gall tissue Later, the medullary rays are affected and also contribute to gall formation The occurrence of sclerenchyma in the host-plant plays an important part in relation to the susceptibility of different varieties of apple to woolly aphis attack The chances of the stylets of the aphid reaching a point near to the cambium bear a definite relation to the degree of development of the prohibiting factor, sclerenchyma The latter tissue, to a large extent, affords a barrier to the passage of the stylets There is also a definite relation between the possibilities of penetration and the number of thin-walled "penetration areas" between the masses of sclerenchyma When the masses of the latter are large, and the softer penetration areas between them are reduced to a minimum, the chances of successful attack are enormously reduced Among the varieties of apple studied it was found that a series arranged according to degree of susceptibility of attack largely corresponds with one arranged in order of the completeness of the development of the sclerenchyma ring

GEOLOGY OF THE GOBI —The geological results of the Asiatic Expeditions of the American Museum of Natural History include a detailed study of the basin structures of Mongolia, a first instalment of which is presented by C. P Berkey and F. K. Morris in the Bull Am Mus. Nat. Hist., vol li., 1924, pp 103-127. Between the Arctic and the Pacific divides lies the Gobi Basin, a down-warped plateau bounded by rims that stand some 3000 feet above its average level. Within it are many minor basins that the authors distinguish by the term *talas* (Mongol for "open steppelands"). Each of these in turn contains still smaller basins which are the *gobis* proper of the Mongols The basement rocks make up a deformed complex that probably corresponds on the whole to the Archæan of other lands, and in particular to the T'ai Shan complex of China. Above these there are probable representatives of the Middle and Upper pre-Cambrian, and all are cut by an immense bathylith Next come infolded remnants of Carboniferous and Permian marine sediments, and a more extensive series of continental clastics that seem to be of Lower Jurassic age All these older formations were strongly folded and worn down to a mature peneplain before the nearly horizontal basin sediments were deposited. These belong to the Cretaceous and Tertiary, and represent a continuation of continental conditions that have persisted right down to the present day Two types of Gobi basins are recognised: one characterised by a faulted margin on the south, where the basins abut against the fault-block ranges of the Eastern Altai, and the other by simple down-warping in the less disturbed areas The faulted basins contain lavas and a much greater thickness of sediments than the warped basins, but in both types sedimentation was intermittent, and in any one basin long intervals are unrepresented by deposits. The Miocene, for example, is almost completely absent from vast areas of Asia On the whole, then, the Angara-Gobia continent seems to have been stable for long periods, and to have suffered regional denudation ever since the (?) Jurassic folding Complementary sedimentation within its own borders is registered only where gentle warping and marginal faulting provided temporary collecting basins

AUSTRALIAN CHINA CLAYS —Australia has large deposits of china clay, and a report has been prepared on their different qualities ("Australian Clays in the Manufacture of White Pottery Wares," by R. C Callister, Bull 27, Institute of Science and Industry, Commonwealth of Australia, Melbourne, 1924) The results are presumably of a preliminary character. Most of the china clay employed in the work was from Lal Lal, and it is said that in this locality "very large quantities were available of a very uniform composition, later it was proved that this uniformity was further increased" when the material from the top was not mixed with that from below, but analyses justifying these statements are not included The ultimate composition is not far removed from that of some of the English china clays The statement that the osmose process of purification has been condemned in America, may convey a wrong impression. Very elaborate and expensive trials on the process have also been made by the British Refractories Research Association, and a few extracts from the report were indicated by Mr. S R Hind in the *Gas Journal* (Supplement, July 9, 1924). The net result showed that the expense did not justify the results obtained by this mode of purifying fireclays. Several countries have deposits of good china clay near at hand, and yet many manufacturers prefer to import the Cornish clays, *e g.* Germany, the United States, etc. Manufacturers have stated that they prefer Cornish clays because (i.) their uniformity can be depended upon from year to year; and (ii.) with other clays there are small losses in manufacture which are a constant and irritating dead-charge on the output. It is to be hoped that the Australian china clays will prove an exception.

AUSTRIAN METEOROLOGY.—In the year-book for 1920 of the Zentralanstalt für Meteorologie und Geodynamik in Vienna, Dr. F. M. Exner directs attention to the number and distribution of meteorological observatories in Austria. There are now 86 observatories, of which 16 are of the first class. The year-book gives the full daily observations at Feldkirch, Salzburg, Sonnblick, Vienna, Graz and Obir, and the monthly and year means for all stations. Further tables give additional data for Vienna from self-registering instruments, while the final section gives the records of air movements derived from pilot balloons at Vienna in 1919 and 1920, to which are added some data from the Hochobir observatory in Carinthia at an elevation of 6700 feet.

FREQUENCY OF HEAVY RAIN IN INDIA.—Memoirs of the Indian Meteorological Department, vol. xxiii. pt. 8, gives much valuable data by Sir Gilbert T. Walker, who was until recently Director-General of Observatories. The object of the discussion is to supply engineering and other projects dependent upon rainfall with trustworthy information regarding both the frequency of heavy rain over various districts of India and the maximum amount of rain to be expected within definite short periods. The observations are for all rain-gauge stations maintained during the period of 30 years from 1891 to 1920, using data only where records are available for at least 10 years, and the number of years is stated. The falls are given for 24 hours, ending at 8 A.M., for the amounts of 3 to 4 inches, 4 to 5, and for each inch to 15 inches, while information of falls exceeding 15 inches in 24 hours is given as footnotes to the ordinary tables. To test the accuracy of the 30 years' limit, frequency tables have been compiled for 8 stations using all available data, the Madras observations cover a period of 85 years and Bombay 76, both of which show the 30 years' results to be quite satisfactory. The tables are grouped for the several divisions. At Cherrapunji, where there are two rainfall stations, the records extend over 30 years; these show a fall of 39 to 40 inches in the 24 hours, and 5 other falls between 30 and 35 inches, while there are in addition 25 falls between 20 and 30 inches in the 24 hours. There are more than ten other stations with a rainfall of upwards of 20 inches in the 24 hours. Rainfall frequencies at five stations in the south of the Bombay Presidency are given in an appendix; these are said to bear out Blanford's statement "that the greatest quantity of rain is yielded by falls not differing very much from those of average measurement." Reference is made to Part 7 of the same volume, which gives the monthly and annual rainfall amounts for all Indian stations to the end of 1920. (See NATURE, June 7, 1924, p. 836.)

MEASUREMENT OF RADIO FREQUENCY.—A paper (No. 489) of more than ordinary interest on the measurement of radio frequency by Grace Hazen and Frieda Kenyon has been published by the Bureau of Standards at Washington. A direct comparison is made between the accurately known frequency of a tuning fork and a high radio frequency. Two intermediate radio frequency generating sets are employed and the adjustments are made by noticing the Lissajous figures produced in a cathode ray oscillograph. The tuning fork had a frequency of 1024·2 periods per second and was driven by a five-watt electron tube generating set. The intermediate generating sets each used a 250-watt electron tube. The oscillograph had a tube of the cold cathode type and required about 20,000 volts to operate it. The Lissajous figures were formed on the fluorescent screen by applying the two alternating magnetic fields at right angles to one another. The procedure adopted was to adjust the frequency of the first intermediate set to be a known multiple of the audio frequency. A range from 1·5 to 22 times the audio frequency was thus obtained. The second intermediate set was then adjusted to the first intermediate set in a similar way. Finally a point on the scale of the high frequency meter was found. The range of the wave meter standardised in this way extends from 3·5 to 5000 kilocycles per second. Photographs of the figures obtained and the apparatus used are given in the paper. The method seems to have been first used by L. M. Hull in 1919. The limitations of the accuracy attainable appear to be entirely in the audio frequency source used as the basis of the measurement and in calibrating and reading the wave meter.

THE ELECTRICAL CHARGE OF THE EARTH.—In a paper in the *Annalen der Physik* for October, Dr. C. Ramsauer directs attention to the fact that, though the surface density σ can be deduced from the potential gradient in the atmosphere by means of the formula $2\pi\sigma = -dV/dh$, a direct measurement requires a definite reference point, which can now be supplied by the state of an electrically neutral atom, containing an equal number of electrons and of protons. This is the state in the interior of every conductor, independently of the distribution of electricity on its surface, and an experiment is described in which an insulated plate A, parallel to and in the plane of the earth's surface, can be covered with a conducting cover B connected to the earth, so that A, which was originally part of the earth's surface, is now in the interior of the earth. A is connected to earth through a circuit containing a galvanometer and a key. The key is pressed down with B removed, the key is raised, B is placed over A, the key is pressed down and the charge on A discharged through the galvanometer. Another current can be produced when the cover is removed and A becomes charged again. It is possible to use an electrometer instead of a galvanometer, if the capacity of the condenser A – B is known. In this way, the excess of electrons for a definite area of the earth's surface is determined; the highest value observed was about 1×10^{10} electrons or 15×10^{-10} coulombs per square metre, on one occasion, during a light shower, the density fell from 14×10^{-10} coulombs per sq. m. to zero in a few minutes. Such variations are due to space charges in the atmosphere, and possibly to the charges of the heavenly bodies.

ZIRCONIUM AND HAFNIUM OXIDES.—G. Hevesy and V. Berglund have determined the densities of zirconium and hafnium oxides by the pyknometer method (J. Chem. Soc., November). X-ray examination showed that the latter oxide contained less than 0·5 per cent. of the former, both oxides were prepared from the normal sulphate and were carefully purified. The average densities obtained were (20°). ZrO_2 5·73, HfO_2 9·67; hence the percentage of hafnium oxide in a mixture of the two oxides is given by the formula $(d - 5·73)/0·0394$, where d is the density of the oxide mixture at 20°. This formula should only be used when both oxides are prepared by exactly the same method.

ERRATUM.—In a note on Mr. J. B. Kramer's paper entitled "An Electronic Battery," in the issue of December 13, p. 873, it was stated that the terminal connected to the carbon is negative, this is incorrect—the terminal connected to the zinc is negative, and that connected to the carbon positive.

Cloud Forms.

THE United States Weather Bureau at Washington has issued a publication [1] which would seem to be intended as a guide to cloud forms for meteorological observers It consists of a short introduction, two diagrams of cloud height frequencies, a page devoted to definitions of cloud forms, taken from the International Cloud Atlas, and 32 photographs of different forms of cloud. The memoir gives in convenient form information which will be useful to meteorological observers, and if any criticism may be made, it is that a few of the photographs are not quite typical and some are not clear

All modern cloud classification is based on the International Cloud Atlas The classification adopted there is based on appearance It is also recognised that form has been found to be largely dependent on height, and American observers argue that "it is therefore possible to gain information concerning the direction and velocity of the wind aloft by assigning the cloud to the height of most frequent occurrence, even though its exact height at the particular time is not known" This method has been widely used, but it has always seemed to the writer to be a procedure of very doubtful validity, especially when applied, as it frequently has been, to cirrus, for although, as we learn from the Weather Bureau Memoir, "the height of maximum frequency both summer and winter was between 8000 and 8400 metres," out of 227 measurements, yet there was a secondary maximum some 2000 metres higher "Seven-tenths of all cirrus observed were found between 7600 and 11,200 metres," which is a fairly wide range, while cirrus has apparently been observed at Blue Hill, Mass., so low as 2400 metres and so high as 15,000 metres

The method of assuming cloud heights and deducing the wind velocity at the cloud level by observing the drift is therefore liable to grave errors; the one theodolite method of observing pilot balloons has been much criticised on the same grounds, but on days when convection currents are not very active, it is not so liable to error as the cloud method One can never be certain without cloud height measurements that one is dealing with a cloud at an average height.

The consideration of the maximum height of cirrus brings to mind the so-called "night shining clouds" observed in the last two decades of the nineteenth century, supposed to be associated with the eruption of Krakatoa They had all the appearance of cirro cumulus, but their height was about 50 kilometres. The highest cirrus measured by A. W. Clayden was 27½ kilometres, there is thus a region of more than 20 kilometres in which clouds have never been observed, and then a level where they have been observed on rare occasions Perhaps it is more than a coincidence that the height of the night shining clouds corresponds with the secondary or lower maximum of meteor disappearance as determined by Lindemann

The two diagrams reproduced here (Figs 1 and 2) give cloud height frequencies for the various forms of cloud, for summer and winter respectively, as observed at Blue Hill, Mass., based upon tabulations for each 400 metres, by H H Clayton These diagrams are extremely interesting, and we wish that similar diagrams could be constructed for other parts of the globe, there must be a considerable body of information which might be made available, for there are to-day more methods than formerly of determining cloud heights. The diagrams show very clearly over what a wide range of height the various cloud forms

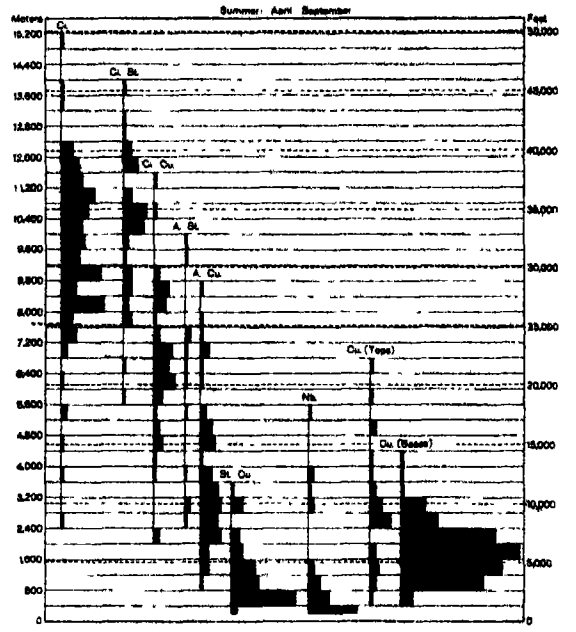

FIG. 1.—Cloud height frequencies, April to September, 1890-91 and 1896-97, Blue Hill, Mass., based upon tabulation for each 400 metres, by H. H. Clayton. Relative frequency is indicated by width of figure. From "Cloud Forms"

extend, alto cumulus overlaps cirro cumulus, and strato cumulus overlaps alto cumulus, and one is tempted to wonder whether there is any essential difference between the three forms, since neither in

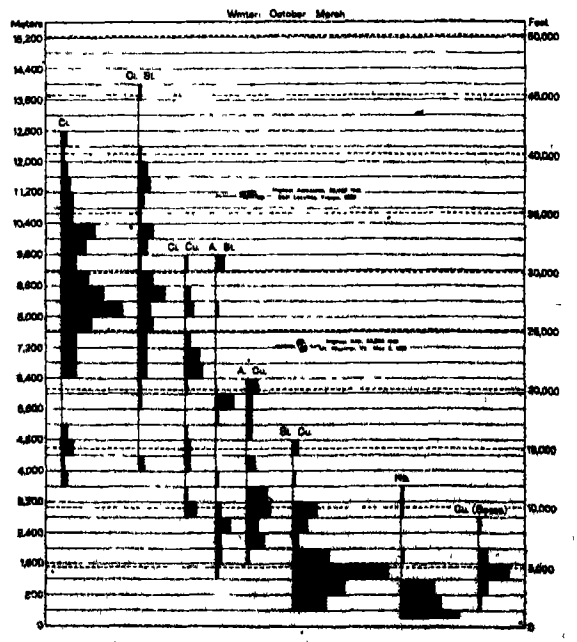

FIG. 2.—Cloud height frequencies, October to March, 1890-91 and 1896-97, Blue Hill, Mass., based upon tabulation for each 400 metres, by H. H. Clayton. Relative frequency is indicated by width of figure. From "Cloud Forms."

[1] U.S. Department of Agriculture, Weather Bureau. "Cloud Forms according to the International System of Classification." Prepared by the Weather Bureau Cloud Committee Benjamin C. Kadel, Harry C. Frankenfield, and Franklin G. Tingley. Pp. 22 (Washington: Government Printing Office, n.d.) n.p.

appearance nor in height is there any line of demarcation. This is indeed recognised, for in one of the photographs, illustrating the Weather Bureau publication, of strato cumulus or alto cumulus, a note is added that "these same clouds would be called strato cumulus by an observer nearer to them and alto cumulus by an observer farther from them (as at sea level)." The heights given for nimbus are curious; the maximum frequency is quite low, 400 metres for both summer and winter, but there are occasional observations at higher levels, one in summer so high as 5000 metres.

The photographs which constitute the bulk of the Weather Bureau Memoir are interesting; and some, such as the undulated alto stratus seen from above at Mount Wilson (Plate 11), and the same form of cloud seen from below at Washington (Plate 13), are very beautiful. There is one remark to which exception might be taken; it occurs as a note under a fine photograph, by Sir David Wilson-Barker, of small alto cumulus, and runs. "Even if there are no shadows the presence of coronas or iridescent colours near the sun or moon distinguish such small alto cumulus from cirro cumulus." In the present writer's experience, iridescence and coronæ are quite common in clouds which would be classified as cirro cumulus.

The Locust Problem and its International Solution.[1]

By Dr. A. D Imms.

IT is a matter of common knowledge that the damage occasioned by locust invasions is frequently extremely serious. Thus, in the year 1874, the destruction brought about by these insects in the Rocky Mountains amounted to approximately forty million dollars In 1908 an estimated damage of one million sterling was caused by locusts to crops in the Transvaal, while the cotton crop in Egypt has often suffered severely. The intensity of an attack, and some idea of the damage done, may be gauged from the number of locusts often found within a comparatively small area. For example, in Southern France in 1920, between twelve and thirty million locusts were destroyed daily, while twenty tons of eggs were collected in a single month in the Argentine in March 1915. Since the year 1914 the countries affected by locusts include the greater part of Africa, certain parts of Spain, France, Italy, Asia Minor, Turkestan, etc The regions more especially affected lie between 20° and 40° latitude north and 15° and 45° latitude south, the equator being comparatively immune. In order to deal with these outbreaks some international organisation appears necessary, and it is to be hoped that the League of Nations will lend its authority to assist in arriving at a concerted plan of action. The need for international action is obvious when it is remembered that locust swarms can travel 18 to 300 miles in a single day, thus easily migrating from one country into another

Very large amounts of money are spent yearly by some countries on preventive measures The danger to public health caused by locust invasion is far smaller than formerly, and the last severe famine due to locust devastation was in 1866. In that year about 200,000 natives perished in North Africa The obstruction and poisoning of wells and other water supplies, however, may still entail very serious consequences

No really adequate biological studies of locusts are available, and knowledge has scarcely yet progressed beyond empirical methods. Much that has been written on the migration and breeding of these insects is sufficiently untrustworthy to demand renewed investigation. Important work, however, has been done by Uvarov, J. C Faure and Hernandez. Among the results achieved, the most important is the demonstration that certain species of locusts have two distinct phases in their development. the migrating or gregarious phase and the solitary or individual phase. Uvarov has devoted attention to the problem of migrations. These are not the result, as commonly supposed, of the necessity of finding fresh food. Locust swarms frequently leave fertile lands for others which are far less so. The factors governing these migrations need renewed study, but they appear to be governed by variations of temperature rather than by the availability of vegetation Important changes in the physiology of the individual locusts have also been observed during migration. Until sufficient biological data are available, emergency action will have to be continued in order to restrict migration and the resulting damage to crops It is to be hoped, however, that the problem will be solved if the States interested will provide for the biological investigation of locusts instead of being satisfied with occasional emergency measures

Methods of control are very varied, and it may be added that the utilisation of natural agents has been insufficiently explored The study of the insects' parasites demands further attention, and we are still not in a position to say whether important results may or may not be expected from this line of work Attempts at propagating bacterial or other diseases have not yet been successful Mechanical methods by means of artificial barriers are numerous, and these provide the means for arresting and destroying locusts in bulk but they are not by any means adequate. Physical methods—the use of fire—have been applied in various ways The modern French method of using the army flame-projector has been employed with great success in Algeria A single charge of 12 litres of crude oil is sufficient to destroy all locusts gathered on a surface of 500 square metres Among chemical methods, the use of poison gas has not proved successful in experiments Among insecticides, arsenate of soda appears to be the most satisfactory compound, and in Italy other methods of destruction have now been abandoned

International conventions for combating these insects first came into being in South America and South Africa. A further important step was taken at the Rome conference of 1920, when thirty-five countries signed a convention naming the International Agricultural Institute as the headquarters of an International Locust Information Bureau Unfortunately, it does not seem that much progress has been made, and the International Institute has not been in a position to publish reports from the Governments concerned except a few from Algeria, Bulgaria, French West Africa, and Hungary. Good work, however, has been done by North African countries, which have concluded a special agreement among themselves. It is to be hoped that effect will be given to the resolutions of the 1920 Convention and that the need of financing skilled biological study of locusts will be recognised. M. Vayssière outlines a scheme of the international organisation he proposes and suggests the League of Nations as being best able to give that assistance necessary to secure effective international co-operation of the kind required.

[1] "Le problème acridien et sa solution internationale." By Paul Vayssière. In *Matériaux pour l'étude des calamités*, No. 2, 1924, pp. 122-158. (Publiés par les soins de la Société de Géographie de Genève.)

Fields of Progress in Chemistry.

THE American Chemical Society has started a new venture in the form of a quarterly issue of *Chemical Reviews*. The first issue contains four articles on "Atomic Weights and Isotopes" (40 pp.), by Prof. T. W. Richards; on "The Constitution of Polysaccharides" (31 pp.), by Principal J. C. Irvine; on "The Theory of Membrane Equilibria" (18 pp.), by Prof. F. G. Donnan, and on "Organic Radicals" (51 pp.), by Prof. M. Gomberg. These four articles were prepared in connexion with the dedication of the Sterling Chemical Laboratory, and are now published as part of the first volume of *Chemical Reviews* by permission of Yale University.

Although prepared for another purpose, the articles may perhaps be regarded as a type to which later *ad hoc* contributions will tend to conform, and may therefore be used as the basis for an answer to the obvious question as to whether a new publication of this kind is likely to be of permanent usefulness. In our opinion, the answer is in the affirmative. Twenty years ago, in 1904, the Chemical Society of London began a series of Annual Reports on the Progress of Chemistry in order "to present an epitome of the principal steps in advance which have been accomplished in the preceding year", and more recently the Society of Chemical Industry has supplemented this work by a series of Annual Reports on the Progress of Applied Chemistry. These annual reports have established themselves as an indispensable supplement and guide to the contents of the Abstracts of the preceding year. Their most obvious limitations are found in two directions. The first is a tendency to "scrappiness," which must always result from the cutting up of a continuous series of experiments into yearly "progress reports." The second is the risk that the personal interests of the reporter in a particular branch of chemistry may lead to the over-emphasis of progress in certain directions, and the neglect of important work in others.

These limitations have been minimised by changing the reporters after a period of perhaps three years, and by encouraging them to trace in some detail the earlier stages of researches in which important progress has been made during the year; but it is clear that the new series of *Chemical Reviews* will have the great advantages that the articles will deal with a small number only of live topics and that the summaries will be authoritative statements by the worker himself, instead of by a reporter. For the general student, who wishes to secure an introduction to current literature, it may very well prove of even greater value than the Annual Reports, and, judging by the earliest samples, they have the merit of being eminently readable, so that it is a pleasure rather than a duty to study them. On these grounds the new publication may be heartily welcomed, as providing in a systematic form the type of publicity that has hitherto only been given spasmodically in lectures and presidential addresses. The price of the publication is five dollars for each annual volume, or four dollars to members of certain cognate societies; it is also proposed, if there is sufficient demand, to issue reprints of the individual articles, so that a whole class can be supplied with copies.

The International Critical Tables.

AT the meeting of the International Union of Pure and Applied Chemistry held in London in 1919, the American delegates submitted a proposal for the international compilation of critically prepared tables of the physical properties of chemical substances and technological materials. The proposal was approved by the Union, and the American National Research Council at Washington has since undertaken the financial and editorial responsibility for the undertaking. A Board of Trustees has undertaken to raise the sum of 200,000 dollars or such part thereof as may be necessary. The editorial responsibility is invested in a Board of Editors, the editor-in-chief being Dr. E. W. Washburn, formerly professor of physical chemistry at the University of Illinois.

To ensure the international character of the Tables, corresponding editors have been appointed in the principal countries of the world. It may be added that the Tables are in no sense a commercial undertaking and the members of the boards of trustees and editors and the corresponding editors serve in an honorary capacity.

The work of critically examining the data and of compiling the various tables is being carried out by well-known chemists, physicists, engineers, etc., some three hundred in number, who have been chosen for this purpose in the various countries of the world, largely on the basis of recommendations from the corresponding editors and their advisory committees. These authorities are not being expected to assume the responsibility of searching the literature, a task which is being carried out in the main by the editorial staff at Washington, but rather to assemble, to examine critically, and to select the best value for each constant, indicating at the same time the probable uncertainty. Each portion of the Tables will be published over the name of the co-operating authority who has assumed responsibility for it, and the size of each assignment has been restricted so that the work may be carried out within a reasonable time and without becoming too great a burden for any individual (or co-operating group of individuals) to bear.

The main language employed in the Tables will be English, but the introduction, table of contents, definitions, general explanatory text, and a very complete index will be in English, French, German, and Italian.

The Tables will contain all available information of value concerning the physical properties and numerical characteristics of (*a*) pure substances, (*b*) mixtures of definite composition, (*c*) the more important classes of industrial materials, (*d*) many natural materials and products, and (*e*) selected data for certain bodies or systems, such as the earth and its main physical subdivisions, the solar and stellar systems, and certain biological organisms, including man.

The scope of the Tables is so immense, and of such an unprecedentedly comprehensive character, that special attention has had to be given to the arrangement so as to enable the Tables to be used with facility and dispatch. For pure chemical substances the data will be assembled in tables of properties, but a certain amount of latitude and duplication will be permitted in some instances, and tables of materials will be employed where it proves to be more convenient. In some cases no definite value of a constant can be put down, but only upper and lower limits. In other cases a graph may be the best means of indicating the variation of the particular property in question.

The importance of securing uniformity in the case

of fundamental constants, conversion factors, etc, has not been lost sight of, nor the importance of associating, where possible, with the data for a particular specimen or material, a statement of the exact experimental conditions, life history, etc

The Tables will be issued in a series of volumes comprising a total of about 2500 pages (10 in. × 7 in.), publication extending over about a year and a half. The progress made has been such that the first volume is now in the press and may be expected during the early months of 1925. The published price of the Tables will be from 60 to 75 dollars for the set, but the trustees are reserving the privilege of purchasing from the publishers at the rate of 35 dollars per set whatever number of sets may be required to fill all advance subscriptions received by the National Research Council of America up to a definite fixed date, probably April 1 or May 1, 1925. This price represents only the cost of printing, but the trustees and the National Research Council are anxious that all scientific men and women shall be given the opportunity of taking advantage of the lower rate. Accordingly, arrangements are being made so that (1) members of a recognised scientific, technical or engineering society, or (2) universities, research laboratories, libraries, government departments or the like, will shortly be given preferential facilities for purchasing sets at the lower figure before the expiration of the above-mentioned date. The National Research Council will deal with such applications, but all orders placed in the ordinary way through the trade will be handled by the publishers at the higher figure

The Advisory Committee for the British Empire (excluding British North America) consists of Dr G. W C. Kaye (corresponding editor), Sir Robert Robertson, Dr W Rosenhain, Prof A W. Porter, Dr. T. E. Stanton, Mr. J. E Sears (jun.), Mr. A. C G Egerton, and Mr W F Higgins as secretary. Dr. Rosenhain is also acting as special editor for metals and alloys. It is requested that any correspondence from the British Isles with reference to the Tables should be addressed to Dr Kaye, The National Physical Laboratory, Teddington, Middlesex

University and Educational Intelligence.

BELFAST.—Dr. J A Milroy has been appointed J C. White professor of bio-chemistry in the Queen's University Dr. Milroy came to Belfast in 1902 as demonstrator in physiology, and on the foundation of the University in 1909 he was appointed lecturer in bio-chemistry. The title of reader in bio-chemistry was conferred on him in 1922. He is the author of numerous articles in the *Journal of Physiology* and other scientific papers

Dr. V. D. Allison has been appointed J C White lecturer in bacteriology in the University Dr. Allison is a graduate of the University, and since 1920 has continued his studies as research student in the Institute of Pathology as a Beit Memorial Research Fellow, working under Sir Almroth Wright and Prof. A Fleming

BIRMINGHAM.—Applications are invited for the professorship of philosophy in succession to Prof. Moberly. Applications (fifteen copies of each), copies of three testimonials, etc., must reach the Secretary of the University by February 2 at latest.

LONDON.—The following doctorates have been conferred:—*D.Sc.* (*Botany*). Miss K. B. Blackburn (Bedford College), for a thesis entitled "The Cytological Aspects of the Determination of Sex in the Dioecious Forms of Lychnis"; *D Sc* (*Chemistry*): Mr Harold Hunter (East London College and Battersea Polytechnic), for a thesis entitled "The Chemical Significance of Optical Dispersion", *D Sc* (*Physics*) Mr A. H Davis, for a thesis entitled "Natural and Forced Convection of Heat in Gases and Liquids," and other papers, Mr. J. H Shaxby, for a thesis entitled "Papers on Molecular Physics," and other papers; Mr J E P. Wagstaff, for a thesis entitled "The Measurement of Short Time Intervals and its Application to (*a*) the Determination of the Velocity of Detonation of Explosives, (*b*) the Duration of Impacts of Bars mainly with rounded Ends, in elucidation of the Elastic Theory," and other papers

MANCHESTER.—Applications are invited for a lectureship in anatomy The latest date for applications is February 11. They should be sent to the Internal Registrar, from whom particulars may be obtained

OXFORD.—Applications are invited from persons possessing a thorough knowledge of entomology in its application to forestry and with experience of tropical conditions for the post of entomologist at the Imperial Forestry Institute Applications, stating age, qualifications, and salary required, and furnishing references and copies of testimonials, with a list, and if possible copies, of published writings, should be submitted not later than April 15, to the Secretary of the Institute

THE official report of the Indian Universities Conference held at Simla last May (Calcutta, Govt of India Central Publication Branch, pp 79 8*d*) gives in full the Viceroy's inaugural address, two addresses by the Minister of Education, Health and Lands, and the 49 resolutions passed by the Conference, and brief summaries of the discussions. The most important outcome of the Conference is the project for an inter-university board Steps have already been taken to bring this into being, a provisional committee having been appointed immediately after the close of the Conference to make further detailed suggestions for the consideration of the universities This it has done, and it is proposed to hold the first meeting of the board in Calcutta, if possible in February next The Conference has, moreover, recommended to the Government of India that a central advisory board for scientific research be constituted in India, comprising the heads of scientific departments of the Government and a representative of science nominated by each of the Indian universities and by the Indian Institute of Science, with power to co-opt representatives of other recognised institutes of science not affiliated to any university. It is intended that this Board should, among other things, co-ordinate scientific publications in India, utilising or combining existing organs and developing them on an all-India basis and recommending to Government cases where financial assistance would be desirable It would consider whether the publications of the Indian Museum and the Botanical Survey of India, the Memoirs of the Geological Survey of India, and the *Agricultural Journal of India*, now issued by Government, should not have on their editorial boards expert representatives of the various universities, and whether the scope of these journals should not be enlarged It would also advise the Government from time to time generally with regard to the promotion of scientific research in India. Another resolution demands the remission of customs duty on scientific apparatus and chemicals imported for the use of universities and other approved educational institutions.

Early Science at the Royal Society.

January 3, 1662/3 The president reported a letter in favour of the society to the duke of Ormonde, lord lieutenant of Ireland—"I am desired by the Royal Society in their names to entreat your grace's favour and countenance in the effectual settlement of the fractions of adventures, arrears, lands, &c., which by the act for the better execution of his majesty's gracious declaration were vested in his majesty, in trust for, and the better to enable his majesty to grant the same to them, so as his majesty being their founder might also be their chief benefactor". [signed Brouncker, P R S]—Sir William Petty who was then in Ireland, was desired to make a calculation of these fractions of adventures &c., which he accordingly did, but did not send the society the result of it, in regard that interest was past before by patent acts unto some others, as he mentions to Sir Robert Southwell, when the latter desired him, in the name of several of the most eminent members of the society, to send over to them his calculations.

January 4, 1664/5 Mr Francis Willughby being come home from his travels [mostly in Spain] and present, was desired to communicate his philosophical observations. He produced a printed cut representing Saturn and Jupiter, and what Campani had lately observed in them by means of his new glasses, wrought by a turn-tool without a mold.

1666/7. Mr Oldenburg read an extract of Mons Auzout's letter to him from Paris, mentioning a new method esteemed by him better than any hitherto practised, of taking the diameters of the planets to seconds, and of knowing the parallax of the moon by means of her diameter. Dr Wren and Mr Hooke having related to the society several ways, which they had known long before of taking the diameters of the planets to seconds, were desired briefly to describe them, that so it might be signified to the Parisian philosophers, that it was a thing not at all new among the English.

January 6, 1663/4. Mr Boyle remarked that swallows frozen up in ice, upon the thawing away of the ice had been found alive, and flying about, and that a minister had sent a certificate of this to the king from Dantzic.—Sir Robert Moray related that he had been informed by his highness the Duke of York, that there were certain little springs at Croyden, which would run together, and make a stream for a certain space, and then slide under the ground, and afterwards break out again. Dr Wilkins having acquaintance at Croyden, was desired to make a particular inquiry after this fact.

January 7, 1662/3. Mr Bruce brought in an account of windmills in Holland, which was ordered to be registered. [We may recall here the reference that was made in NATURE, of Sept. 13, to the acquisition by the Franklin Institute in 1922, of a collection of books and pamphlets on windmills, inclusive of treatises on the subject in German and Dutch, 17th and 18th centuries.]

January 8, 1661/2. Sir Robert Moray communicated letters, in French, from Mons. Frenicle to Mons. Huygens, concerning the hypothesis of Saturn.—Mr Rooke read a paper of inquiries to be made in the East-India captain's voyage to Bantam.—It was ordered that all the papers of inquiries for foreign parts be written out into one paper.

1672/3 There was produced to the society a discourse of Dr. Grew, concerning his whole design with respect to vegetables, and the means of effecting it. Part of this discourse was read, to the great satisfaction of the Society who urged the publication of it.

Societies and Academies.

LONDON.

Royal Anthropological Institute, December 9.—H. **Balfour**: The origin of the art of stencilling in the Fiji Islands. The use of stencils in the Fiji Islands, for decorating bark-cloth, does not appear to have been introduced into the group from the outside, and it was suggested that the stencil designs, which are cut in leaves almost invariably, may very probably have been suggested by leaves which have been tunnelled by insect larvæ while still in the tightly rolled up state of the budding leaf. The leaves, when they unroll in the course of their development, exhibit transverse alignments of regular perforations, which bear a striking resemblance to some of the simpler Fijian stencil designs.

PARIS.

Academy of Sciences, November 24.—L. **Lecornu**: The tetrahedral system. Lowthian Bell, in 1875, regarded the earth as possessing a symmetry analogous with that of a regular tetrahedron. This question has been examined by several geologists; the author submits it to a mathematical analysis, applying the theory given in a recent note (*Comptes rendus*, t. 179, 1924, p. 853) on the deformation of a spherical envelope.—J. and Mlle. M. **Bordet**: The bacteriolytic power of colostrum and milk. Colostrum exerts a powerful bacteriolytic action upon organisms commonly present in the atmosphere. This confirms the work of Jensen (1905) and of F. Smith and Little (1922).—W. **Kilian**: The fluvio-glacial deposits of the southern bank of the lake of Geneva and their hydrological regime (Evian, Amphion, Thonon).—Jules **Andrade**: A curious theorem of metrology and its applications to chronometry.—P. J. **Myrberg**: A generalisation of the linear equations of finite differences.—E. F. **Collingwood**: The exceptional values of integral functions of finite order.—Nikola **Obrechkoff**: The convergence of trigonometrical series.—Paul **Mentré**: The non-special complexes with multiple inflectional focus.—D. **Riabouchinsky**: Some considerations on the plane rotational movements of a liquid.—P. **Idrac**: Theoretical study of the flight of the albatross in a wind increasing with the altitude.—Charles **Nordmann** and C. **Le Morvan**: Variable stars with continuous variation and Ritz's hypothesis. de Sitter has adduced observations on double stars as evidence in favour of the constancy of the velocity of light. La Rosa has criticised these views and concludes that observation of these stars proves nothing for or against the hypothesis of a constant velocity of light. The authors have shown that the amplitude of the light variation of variable stars with continuous variation is not the same in different regions of the spectrum. This experimental fact the authors consider invalidates the extension of the ballistic hypothesis of Ritz, as given by La Rosa.—F. **Baldet**: Observations of the planet Mars with the 83 cm. telescope of the Meudon Observatory. Reproductions of six drawings of the planet are given, taken between September 5 and 28. All the observations detailed confirm those already published by Antoniadi. No trace has been found of the geometrical network of filiform "canals."—J. **Guillaume**: Observations of the sun made at the Observatory of Lyons during the second quarter of 1924. Observations were possible on 83 days during the quarter. The results are summarised in three tables, showing the number of spots, their distribution in latitude, and the distribution of the faculæ in latitude.—Rafael **de Buen**: Some observations on the course of the currents in the Straits of Gibraltar.—

P **Gaubert**. The circular polarisation of the light reflected by insects Detailed examination shows that the insect behaves as though the cuticle which surrounds it had been cut out of a single sheet of tissue capable of polarising light circularly Two hypotheses are examined, in which the presence of liquid crystals is assumed Cholesterol melts at 147° C, and as the polarisation phenomena do not completely disappear below 300° C, the presence of this substance does not afford an explanation — L **Décombe** Electrified spherical films The direct calculation of the constant of gravitation as a function of the constants of Avogadro, Faraday, Rydberg, and Planck --Ch. **Féry**. A lead accumulator incapable of being sulphated The fundamental equation governing the working of the ordinary secondary battery is assumed to be

$$2Pb + H_2SO_4 + Pb_2O_5 \rightleftarrows Pb_2SO_4 + 2PbO_2 + H_2O$$

According to this view, lead sulphate, $PbSO_4$, is not formed during a normal discharge The spontaneous discharge of an accumulator on standing is regarded as due to the combined action of oxygen and the electrolyte on the negative plate

$$2Pb + H_2SO_4 + O = Pb_2SO_4 + H_2O,$$

with a secondary reaction

$$Pb_2SO_4 + H_2SO_4 + O = 2PbSO_4 + H_2O$$

To avoid the last reaction it should be sufficient to prevent access of oxygen to the negative plate A description is given of a new form of accumulator designed to fulfil this condition This battery retained 33 per cent of its charge after standing 26 months, corresponding with a discharge of 4 per cent per month If discharged, and allowed to stand two years, it could be recharged normally -- Victor **Henri** and C **Teves** The absorption spectrum of sulphur vapour as depending on the constitution of the molecules The molecules S_8 and S_6 present a structureless continuous absorption spectrum The S_2 molecules possess an absorption spectrum formed of a very large number of bands, the structure of which is analysed in detail (*v* also NATURE, December 20, p 894) -- M **Bourgeaud** and A **Dondelinger** Researches on the affinity constant of some organic bases —D **Yovanovitch** and J. **d'Espine**. The magnetic spectrum of the high velocity β-rays of mesothorium 2 Two of the lines have velocities 0·998 and 0 986, compared with the velocity of light taken as unity.—A **Vila** The reduction of sulphuric acid to hydrogen sulphide The vapours of sulphuric acid mixed with an excess of hydrogen and passed over silica at a red heat (700° C. to 900° C) give almost theoretical yields of hydrogen sulphide — L. J. **Simon** and V. **Hasenfratz** The lactone of *l*-arabonic acid and some of its derivatives —Ch **Courtot** and A. **Dondelinger**. The α-halogen derivatives of indane —C **Kohn-Abrest** The gases in fresh, putrefied, and frozen blood. Application of the method described in a previous paper to the determination of carbon dioxide, oxygen, nitrogen, and sulphuretted hydrogen in blood It is shown that freezing blood not only arrests putrefaction, but also removes some hydrogen sulphide if this has been already produced by putrefaction.—Y **Milon**. The fauna and the age of the Waulsortian limestones of Saint-Pierre-la-Cour —G. **Mouret** The true prolongation, at Bourganeuf (Creuse), of the Argentat fault and the nature of the supposed schists and gneiss of that region —Louis **Barrabé** and Pierre **Viennot**. The discovery of an oil-bearing layer at Gabian (Hérault). This boring has been carried to a depth of 107 metres, and the present hourly yield of crude oil is between 500 and 600 litres The oil has a density of 0·846 at 15° C, contains 10 per cent. of wax and only traces of asphalte —Gabriel **Guilbert**. The case of destruction of a cyclone —Ph **Schereschewsky** and Ph **Wehrlé** Polar pseudo-fronts — H **Colin** The formation, distribution, and circulation of inulin in the stem of the Jerusalem artichoke. —J **Chaze** Attempts at pure cultures of a Saprolegnia —Marc **Bridel** The presence of very large quantities of free maltose in the fresh tubercles of *Umbilicus pendulinus* These tubercles contain large quantities of maltose as a food reserve, and it has been possible to obtain nearly 4 per cent in the crystalline state This is the first time that maltose has been directly extracted in the crystalline state from plants —R **Cerigneli** Indol in the flowers of Spanish jessamine (*Jasminum grandiflorum*) Indol is a normal constituent of the flowers of this plant. —J **Chaussin** Study of the soluble medium and the insoluble tissues in the course of the development of wheat the influence of a complete mineral manure. —Lucien **Daniel** Heredity in grafted plants --M. **Munerati** Contribution to the study of the appearance of sex in dioic plants —L. **Mercier** The action of naphthalene vapour on *Calliphora erythrocephala* Study of the microscopic lesions presented by the individuals showing malformation —L. **Leger** A new crayfish in French waters — P. **de Beauchamp** The appearance of variations under experimental conditions in rotifers of the genus Brachionus — R **Herpin** The swarming of *Perinereis Marioni* The evolutive cycle of *Platynereis Dumerilii* —Ph **Joyet-Lavergne** The cytoplasmic characters of sexuality in the Gregarinæ — W **Vernadsky** The representation of the chemical composition of living matter — Mlle Eliane **Le Breton** and Charles **Kayser** The metabolism of the purins in diabetes —Mme L. **Randoin** and H **Simonnet** Growth and maintenance of the rat submitted to an artificial diet deprived both of factor B and glucides — C **Dawydoff** The return of *Lineus lacteus* to an embryonic state under the influence of starvation — C **Lebailly** Flies play no part in the dissemination of aphthous fever

VIENNA.

Academy of Sciences, November 13 —F M **Exner** The pressure of sand-hills Attempts have been made to measure the pressure on a plane undersurface of sand masses thrown up with maximum slopes The pressure values in the middle of the base were about those of water columns of the same height, although the density of sand is 1 5 Towards the edges the pressure decreases more slowly than would correspond to the height of the sand This is because the side columns, in consequence of friction, bear part of the weight of the central columns Hyperbolas drawn between the sloping surfaces as asymptotes correspond to this pressure distribution The idea can be applied to determine the form of the compensation defect masses below sea-level in the theory of isostasy —F **Pollak** The kinetics of dissolved gases I The evaporation of carbon dioxide from watery solution into a stream of bubbles of an indifferent gas —M. **Kohn** and G **Loff** VIII. Communication on bromo-phenols Bromo- and bromo-nitro-resorcin —M **Kohn** and G **Löff** On styphnic-acid-mono-methyl-ether and a new trinitro-guaiacol —M. **Kohn** and R. **Lakner** On the action of magnesium-phenyl-bromide on bromo-ethyl-phthalamide —A **Kieslinger** Report on geological and petrographic researches in the Southern Kor Alps on the boundary of Styria and Carinthia. These include (*a*) old crystalline, Teigitsch series, etc, (*b*) diaphthorite zone, (*c*) Mahrenberger series, (*d*) Tertiary covering —J. **Kaesz** Solution of the Delian problem by compasses and ruler.—H. **Priesner** New Thysanoptera.

Official Publications Received.

Diary of Societies.

SATURDAY, JANUARY 3

GEOGRAPHICAL ASSOCIATION (Annual Meeting) (at London School of Economics), at 9.30 A.M.—S. W. Rider and Capt. T. K. M. Booth: Discussion on School Geography.—Miss A. Hicks and others: Discussion on The Beginnings of Geography.—J. A. Mortlock, Miss J. A. Hardy, and others: Discussion on The Teaching of Climate.—Miss L. C. Read, C. C. Carter, and others: Discussion on Home Geography.—Mr. Cattell-Jones, Rev. J. I. Miller, and others: Discussion on School Geography Clubs and Journeys.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—F. Balfour Browne: Concerning the Habits of Insects (IV.): The Habits of the Dragonfly.

GILBERT WHITE FELLOWSHIP (at 6 Queen Square, W.C.), at 3.—Dr. W. Martin: Gilbert White as Antiquary.

MONDAY, JANUARY 5

MATHEMATICAL ASSOCIATION (at London Day Training College), at 10.20 A.M.—Prof. J. E. A. Steggall: The Neglect of Arithmetic in Schools.—A. Buxton: An Application of the Bessel Functions to a Problem in Optical Resolution: Discussion on Tangency and Limits in Geometry.

EUGENICS EDUCATION SOCIETY (at University College), at 11.—National League of Health, Maternity, and Child Welfare.—Dr. J. A. Hadfield: Mental Health of the School Child.

ROYAL DUBLIN SOCIETY, at 4.—Lecture adapted to a Juvenile Auditory.

VICTORIA INSTITUTE (at Central Hall, Westminster), at 4.30.—Brig.-Gen. Sir Wyndham Deedes: Great Britain and the Palestine Mandate.

BRITISH PSYCHOLOGICAL SOCIETY (Education Section) (at University College) at 6.—Dr. P. B. Ballard, T. Raymont, and others: Discussion on the recent Report to the Board of Education on Psychological Tests of Educative Capacity.

ARISTOTELIAN SOCIETY (at University of London Club), at 8.—Prof. G. Dawes Hicks: The Dynamic Aspect of Nature.

SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Chemical Society), at 8.—W. Irwin: An Early Chapter in the Benzol Industry.

INSTITUTION OF THE RUBBER INDUSTRY (London Section) (at Engineers' Club), at 8.—A. Healey: Mechanical Structure of Rubber.

SCIENCE MASTERS' ASSOCIATION (Annual Meeting) (at University of Leeds), at 8.45.—Sir Berkeley Moynihan, Bart.: Presidential Address.

TUESDAY, JANUARY 6

SCIENCE MASTERS' ASSOCIATION (Annual Meeting) (at University of Leeds), at 10 A.M.—Prof. J. H. Priestly: Peat and the Plants that Grow upon it.—A. Yorkshire Problem.—C. B. Fawcett: The Distribution of Population.—At 12, Prof. R. Whiddington: The Trend of Modern Physics.—Prof. R. W. Whytlaw Gray: The Inert Gases.—At 5.30, Prof. W. Garstang: The Songs of the Birds.

MATHEMATICAL ASSOCIATION (at London Day Training College), at 2.30.—Prof. G. H. Hardy: What is Geometry? (Presidential Address).—Dr. H. B. Heywood: The Reform of University Mathematics.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—F. Balfour Browne: Concerning the Habits of Insects (V.): The Habits of the Water-Beetle.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY (at Manchester), at 3.30.—Dr. J. E. Myers and F. Fairbrother: A Few Chemical Curiosities.

ASSOCIATION OF UNIVERSITY WOMEN TEACHERS (at University College) at 5.—Prof. F. Soddy: The Economics of Life.

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5.30.

INSTITUTE OF MARINE ENGINEERS, at 6.30.—C. H. Wright: Some Considerations in connexion with the Measurement of Liquid Fuel Storage and Liquid Depths.

INSTITUTION OF ELECTRICAL ENGINEERS (North-Western Centre) (at 17 Albert Square, Manchester), at 7.

INSTITUTE OF METALS (Birmingham Section) (at Chamber of Commerce, Birmingham), at 7.—T. H. Gant: Cobalt: Its Production and Some of its Uses.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Scientific and Technical Group), at 7.

INSTITUTION OF AUTOMOBILE ENGINEERS (Coventry Section) (at Broadgate Café, Coventry), at 7.15.

WEST YORKSHIRE METALLURGICAL SOCIETY (at George Hotel, Huddersfield), at 7.30.—The Value of some Workshop and Laboratory Tests.

RÖNTGEN SOCIETY (at British Institute of Radiology), at 8.15.—Dr. N. S. Finzi: Some Developments in Deep-Radio Therapy.

WEDNESDAY, JANUARY 7.

SCIENCE MASTERS' ASSOCIATION (Annual Meeting) (at University of Leeds), at 10 A.M.—Prof. A. Smithells and others: Discussion on the Connexion between Science Teaching in Schools and Universities.

ROYAL SOCIETY OF ARTS (Dr. Mann Juvenile Lectures (1)), at 3.—Lt.-Col. G. M. Richardson: Dogs in War.

ROYAL DUBLIN SOCIETY, at 4.—Lecture adapted to a Juvenile Auditory.

GEOLOGICAL SOCIETY OF LONDON, at 5.

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section), at 6.—Prof. E. Mallett and A. D. Blumlein: A New Method of High-Frequency Resistance Measurement.

INSTITUTION OF HEATING AND VENTILATING ENGINEERS (at Engineers' Club), at 7.—O. Stott: Water Gauge.

SOCIETY OF CHEMICAL INDUSTRY (Bristol Section) (at Bristol University), at 7.30.

JUNIOR INSTITUTION OF ENGINEERS (at Royal Society of Arts), at 7.30.—Dr. A. Russell: Presidential Inaugural Address.

ROYAL MICROSCOPICAL SOCIETY (Biological Section), at 7.30.

THURSDAY, JANUARY 8

LEAGUE OF NATIONS UNION (at University College), at 11.30.—Prof. H. G. Fleure: Geography and the League of Nations.

CHILD-STUDY SOCIETY (at University College), at 3.—Prof. E. W. MacBride: The Evidence for the Existence of Environmental Influence on the Course of Heredity.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—F. Balfour Browne: Concerning the Habits of Insects (VI.): The Habits of Insects and the Work of Man.

LINNEAN SOCIETY OF LONDON, at 5.

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—H. W. Taylor: Three-Wire Direct Current Distribution Networks: Some Comparisons in Cost and Operation.

INSTITUTION OF ELECTRICAL ENGINEERS (Dundee Sub-Centre) (at University College, Dundee), at 7.30.—F. J. Lawson: Telephone Cable Practice.

INSTITUTION OF ELECTRICAL ENGINEERS (Irish Centre) (at Trinity College, Dublin), at 7.45.

ROYAL SOCIETY OF MEDICINE (Obstetrics and Gynæcology Section), at 8.—J. P. Maxwell: Osteomalacea in China.

INSTITUTION OF MECHANICAL ENGINEERS (Glasgow Branch) (at Glasgow).—L. A. Legros: Traction across Rough and Roadless Country (Lecture).

INSTITUTION OF MECHANICAL ENGINEERS (Cardiff Branch) (at Cardiff).

FRIDAY, JANUARY 9.

ROYAL DUBLIN SOCIETY, at 4.—Lecture adapted to a Juvenile Auditory.

ROYAL SOCIETY OF ARTS (Indian Section), at 4.30.

ROYAL ASTRONOMICAL SOCIETY, at 5.

PHILOLOGICAL SOCIETY (at University College), at 5.30.—Miss Beatrice Saxon Snell: Anglo-French Building Terms.

SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (at 16 St. Mary's Parsonage, Manchester), at 7.—N. Simpkin and F. S. Sinnatt: The Melting Point of Coal Ash: Part 2.—Prof. H. S. Taylor: The Properties of a Catalytic Surface.

WEST CUMBERLAND SOCIETY OF CHEMISTS AND ENGINEERS (at Workington), at 7.—E. H. Todd: The Structure of Matter.

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7.—The Maintenance of High-Compression Oil Engines.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—A. Keighley: Colour and Sunshine, Some Mountain Villages of Southern France.

INSTITUTE OF METALS (Sheffield Section) (at Sheffield University), at 7.30.—A. H. Mundey: Die-casting.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Literary and Philosophical Society, Newcastle-upon-Tyne), at 7.30.—J. L. Taylor: Theory of Longitudinal Bending of Ships.

INSTITUTION OF MECHANICAL ENGINEERS (Leeds Branch) (at Leeds).—H. W. Bannister: The Scientific Treatment of Boiler Feed-Water.

INSTITUTION OF MECHANICAL ENGINEERS (Liverpool Branch) (at Liverpool).—L. A. Legros: Traction across Rough and Roadless Country.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Middlesbrough Graduate Section).—R. F. Battey and J. Black: Debate on Diesel Engines: Four-Cycle v. Two-Cycle.

SATURDAY, JANUARY 10.

INSTITUTE OF METALS (London Section) (at Institute of Marine Engineers), at 7.30.—Dr. R. H. Greaves: Extensometers.

SATURDAY, JANUARY 10, 1925.

Science and Administration in East Africa.

THE members of the East African Parliamentary Commission, who returned to England on December 23, have not only a remarkable itinerary to record even in these days of rapid travel, but also, according to reports received from the five territories which formed the subject of their inquiries, a notable performance of work under peculiarly trying conditions. Moreover, their visit has been of special significance to scientific workers. Major Church, whose warm advocacy in Parliament of the claims of science to the greater support of the country and his exposition of the function of science in economic development led to his being charged with the responsibility of reporting on the scientific and medical services, and Mr Ormsby-Gore, Chairman of the Commission and again Under-Secretary of State for the Colonies, have both given abundant proof in their public utterances of their appreciation of the scientific aspect of the problems of East Africa ; their realisation of the imperative need for the augmentation of staffs of existing scientific departments ; for the re-establishment of scientific institutions which have been either abolished or neglected ; and for the provision of funds for a campaign against the greatest scourge in equatorial Africa, the tsetse fly.

To scientific workers in East Africa particularly, the visit of the Commissioners must have been a source of lively satisfaction, for they have been given little sympathy or encouragement in recent years. The appointment of the Economy Committee in Great Britain in 1922 for the purpose of reducing expenditure in public departments set an example to the colonial governments. But while the recommendations of Sir Eric Geddes for the crippling of our home research and technical services were tempered by the growing consciousness among all classes in England of the important part played by science in industrial development, those of his prototypes in East Africa met with no such opposition. Science departments were regarded generally as luxuries, and were either "axed" completely or made aware that their continuance for more than another year or two was contingent upon some tangible and material proof of their economic value. For example, the discovery of a rich gold reef by a geologist singly responsible for the geological work of a territory the size of Great Britain might be accepted as a justification for his continued existence. A suggestion by the victim that the discovery of minerals of economic importance was not his primary function, or that such discoveries could best be attained by a scientific and systematic examination of the geology of the country, would probably have been regarded, by the legal luminaries and administrative officers to whom was generally entrusted the task of reducing expenditure, as a confession of incompetence.

Although in the past year the ravages of disease among the human and animal population ; the desiccation of certain hitherto fertile tracts of country due to unrestricted forest fires ; the impoverishment of the soil and the increase of insect pests due to indiscriminate grass burning ; the urgency of the need for local supplies

of fuel for transportation, industrial and domestic needs other than timber; the clamour of settlers and natives and merchants for the protection of economic crops against insect pests and diseases due to their partial realisation of the grave consequences attendant upon the neglect of precautionary measures, have had their effect upon the governments concerned, there remains yet considerable confusion of thought regarding the application of science to these matters The mentality still exists which would starve research in tropical diseases because there had been no recent calamitous outbreak, would contemplate with equanimity the expense entailed by the forced removal of a population of tens of thousands from an infected area when disease overtakes it, but once the immediate catastrophe was past, relapse into the old indifference to research

It is fortunate indeed that men like Mr. Ormsby-Gore and Major Church were members of the Commission They made a special point of meeting every scientific officer available. In Northern Rhodesia the Commissioners met Dr May, who for many years has advocated heroic measures against the tsetse fly. Dr Dixey, the Nyasaland geologist whose recent discovery of dinosaur remains has aroused considerable interest in Great Britain, and whose discovery of coal in the Chiromo district with indications of a coalfield of vast dimensions is of the utmost importance to East Africa, was able to show Major Church round the scenes of his labours and to indicate what was urgently required in the nature of a geological survey. In Tanganyika Territory, Dr. Shircore and Dr. Butler discussed with him their divergent views regarding the relation of yaws and syphilis. Dr. Scott was able to show the tremendous improvement that he has effected in the sanitation of Dar-es-Salaam, which promises to eradicate malaria in this district. The Commissioners travelled far through the fly belts with Mr. Swynnerton, whose heroic measures against the tsetse fly will establish his reputation as one of the foremost personalities in East Africa. They visited also the Veterinary Research Laboratory at Mpapwa, where Mr Hornby is conducting a series of remarkable experiments to test the relative values of hyper-immunisation and immunisation In Uganda they met the important staff, consisting of Dr. H. L Duke, Dr G D. H Carpenter, and Mr. Fiske, whose investigations into sleeping sickness must form the basis of any campaign for the removal of this human scourge. There also Mr. Wayland and Mr. Simmons, the geologists, gave them a greater insight into their purely scientific work and their discoveries of oil in the vicinity of Lake Albert Nyanza than the mere perusal of their official report would indicate; and in Kenya Colony they were able to judge dispassionately of the effect of decentralisation of the research laboratories which followed the departure of Mr. V. H. Kirkman to Zanzibar. The visit to the Amani Institute in Tanganyika a few days before departing from Mombasa convinced Mr. Ormsby-Gore and Major Church also of the urgent necessity of carrying on the work started by Zimmerman under the German Government.

The Chairman of the Commission, in his public utterances, brought home to our East African communities the grave character of tsetse fly domination. Many of his hearers learned for the first time that two-thirds of Tanganyika Territory is practically unfit for human or animal occupation through the activities of this insect and that in every territory visited the fly is increasing. He suggested that the malign influence of the tsetse fly upon tropical Africa is such as to merit the endowment by all civilised countries of a group of research workers to investigate the special problems connected with it.

Major Church did well to remind his Mombasa audience of the disadvantages of parochialism, giving the decay of the Amani Institute as an illustration of his theme. Although that great botanical research institute is ideally situated for carrying out work of vital importance to the whole of tropical Africa, intercolonial jealousies have led each colony to evade making a contribution to its upkeep, with the inevitable results. He tentatively suggested also that the new bacteriological laboratories at Entebbe in Uganda might be supported by at least four of the East African territories owing to its advantages of situation. In the same way, the Veterinary Research Laboratory at Nairobi in Kenya Colony, founded by Mr. Eustace Montgomery, Veterinary Adviser to the Lake territories, might be considered as the principal veterinary research centre for East Africa, although the claims of the Mpapwa Laboratory in Tanganyika to this distinction must be considered. Both Dr. Walker at Nairobi and Mr. Hornby at Mpapwa have much to gain by association under one roof. On the other hand, the establishment of a research centre for investigations in connexion with tropical diseases other than sleeping sickness would be extremely costly, and in view of the present divergent lines of inquiry, and the sharp conflict of opinion regarding the nature of certain diseases, it is doubtful whether any advantage is to be gained at present by centralisation. But apart from any decision of the five territories to pool their resources to establish research centres catering for the needs of their populations, the need for co-ordination and co-operation between them is imperative.

Unfortunately, while it is admitted that the departments entrusted with human and animal pathological research are inadequately supported, in certain territories there is practically no provision for research of any kind. Not even the important discoveries of Dixey of Nyasaland, or the work of Wayland and Simmons in Uganda, have sufficiently stirred the imaginations of the members of the legislative councils in the other three territories to stimulate them to create geological departments. Very little systematic research is being done in these same three territories in connexion with their economic crops, namely, cotton, maize, coffee, sisal, and wheat, while the possibilities of cinchona plantations have never been explored.

It is hoped that this state of affairs will soon be remedied. Backed by the authority of the Commissioners, there should no longer be any excuse for timidity on the part of colonial governors, most of whom personally are fully alive to the necessity for scientific research, and it is sincerely hoped that they will without delay put bold estimates for its prosecution before the members of their respective Legislative or Executive Councils.

Roman Britain.

(1) *The Roman Occupation of Britain: being Six Ford Lectures delivered by F. Haverfield, now revised by George Macdonald, with a Notice of Haverfield's Life and a List of his Writings.* Pp. 304 + 9 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1924.) 18*s.* net

(2) *Roman York: the Legionary Headquarters and Colonia of Eboracum.* By Gordon Home. Pp. 204 + 30 plates. (London: Ernest Benn, Ltd., 1924.) 12*s.* 6*d.* net.

THE Ford lectures of the late Prof. Haverfield were delivered at Oxford in 1907. At the time of their delivery it could be said by the man best qualified to judge, "that the enquiry into the history and character of Roman Britain, with all its defects and imperfectations, has been carried much farther than the enquiry into Celtic or Saxon Britain, much farther, too, than the enquiry into any other Roman province, and that our scientific knowledge of the island, however liable to future correction and addition, stands by itself among the studies of the Roman Empire." It was, in fact, high time for such a summary of results and retrospect of the course of inquiry as might be expected from a Ford Lecturer.

(1) Haverfield was not, however, the man to publish immature work. To those who were privileged to hear them, even if they had worked with him and for him—and he had more truly founded a school than any of his contemporaries at Oxford—the lectures of 1907 were a revelation. Yet publication was postponed, the multifarious calls upon the time of a man as efficient and thorough in university business as he was in the direction of research; then the War, the separation of a man capable of great friendships from continental colleagues, the loss of so many of those younger men whom he had trained and inspired; the more urgent need, as it might well seem, to press on with current work and raise a new generation of workers—all this intervened; and the lectures appear now as a memorial volume, at once of their distinguished author and of the three hundredth anniversary of the Camden chair of ancient history, which he filled with such vigour and distinction.

The necessary revision of the drafts, and expansion on the lines projected by Haverfield himself, has been admirably done by Dr. George Macdonald. He has also supplied an intimate study of the man and his life's work, and a bibliography which, though limited to signed articles, and exclusive of book reviews, fills no less than eighteen printed pages, and runs to as many as twenty-five items within a year.

The study of Roman Britain is an instructive example of the ups and downs of scientific method. Quite early in the Saxon period, the standing monuments of Roman occupation, and the folk-memories of the surviving British, challenged attention and comment, and on the British side of the breach, there were traditions older still, of the coming of the Romans, and of Celtic resistance to them. There has never, therefore, been a time when the written history of our island did not begin with a retrospect of "Roman Britain." In the twelfth and thirteenth century renaissance, which gave us the University of Oxford, it was the same, with the new habit added, of describing the monuments, deciphering inscriptions—more generally practicable then than now, for a generation whose learned language was still Latin—and attempting to identify places and lines of communication.

The achievements, in this direction, of men like Henry of Huntingdon and Geoffrey of Monmouth, have been the sport and the despair of their successors; and their ghosts still haunt the local antiquary. Even quainter disservice was done by renaissance scholarship abroad, whereby, in great ignorance of topography or philology, "obsolete names of cities are set forth in modern fashion," as in Servetus's edition of Ptolemy. But the "Britannia" of William Camden was recognised, at its first publication in 1586, as opening a new era of research. It stands, indeed, by the side of the classics of natural philosophy as a pioneer of the "advancement of learning" Camden, however, though a great antiquary, was not a first-class scholar, nor of scrupulous accuracy or self-criticism among the temptations which beset all historians, and some of his fertility of imagination and slovenliness in detail has descended upon lesser men, along with his inspiration to systematic field-work Other handicaps were, the disfavour into which the Society of Antiquaries fell under James I., the divorce between this London institution, after its revival in Stukeley's time (1717–18), and the literary scholars of the Universities; and Stukeley's disastrous acceptance of the forged "Richard of Cirencester," which perverted almost everything that was written on Roman Britain for a full century after 1757

It was only gradually that the Roman occupation of Britain came to be conceived either as a well-marked and peculiarly self-contained phase of British history, or as the local aspect of Roman imperialism. The antiquarianism of the eighteenth century was the hobby of a few able amateurs Camden's classification of antiquities by counties stimulated much county-history and local patriotism of a competitive kind, but few attempts to comprehend either whole periods or natural regions. Then, the new movement in scientific thought which escorted revolutionary politics,

and the æsthetics of romance, found one of its characteristic expressions in a philosophy of history, and another in the regional studies appropriate to an age of nationalism. While Niebuhr, Ranke, and Mommsen were making history scientific, the squirearchy and the "literary and philosophical" societies made archæology popular and fashionable The "new rich" of the early nineteenth century, as of the seventeenth and the twentieth, followed the fashion; became collectors and sometimes connoisseurs; and the "classical" education administered, for similar reasons, to their sons perpetuated an acquaintance with Cæsar's work, at all events, as part of the outfit of a gentleman, though at some risk to his knowledge of either history or geography.

Probably there are few countries even now in which an interest in "Roman remains" lies so near the threshold of consciousness as in Great Britain, few, however, in which the notion of them as a subject of scientific investigation was, until recently, so remote even from the minds of many scholars

The last generation of explorers, indeed, has had almost as much to undo as to create. The ancient divorce between university scholarship and regional field-work, which was notorious in Camden's time, persisted within living memory; and in so far as they have been reconciled, it has been the work of two men, Haverfield himself and Pelham, his predecessor in the Camden chair. The characteristic English disbelief in anything systematic or expert, whether in training or in research, is hard to defeat. the distance between London and the older Universities hampers intercourse between literary scholars and the national storehouse of antiquities, the "little learning" of the local antiquary, and his invincible antipathy no less to the use of modern languages than to continental methods of study, have stultified the benevolence of local patrons, which has often been generous.

For this state of things there are two remedies, illustrated respectively by the two books under review: better scholarship and wider background of knowledge on the part of the local field-worker—and a book like that of Mr. Home on Roman York would have been impossible twenty years ago—and closer and more persistent supervision and correlation of the field-worker by what may justly be described as a head-quarters staff. For, as Haverfield frankly concludes, in his first Ford lecture, the reforms effected by Mommsen in particular in Roman history during the nineteenth century "make it doubtful if the amateur can in the future do any real good." "The whole subject has become much harder"; for "to-day, unfortunately, accuracy is necessary"; and if we seem not to know now a good many things which passed current with antiquaries half a century ago, it is due to ruthless critical revision by a few men of scientific training and experience.

This critical revision of our knowledge of Roman Britain has various opportunities and lines of approach, as the lectures in question demonstrate. The older historical geography dealt with political boundaries "described pictorially on a series of vari-coloured sheets": it is quickly giving place to a "wider and a wiser view" of the relations of geography and history, which "begins by studying the physical features of the world by themselves," and only afterwards attempts, in the light of this knowledge, "to deduce the influence of these physical features in any special period." Only so, as in the first lecture of this series, can the strategy, for example, of Claudius's campaign of conquest in A.D. 43 be appreciated, and the later operations of Agricola, Hadrian, or Ulpius Marcellus, and the revolt of Boadicea, or of the North in the days of Commodus, be set in their true perspective. Only so, too, in the light of continental work on the defences of other frontiers of the Empire, on the Rhine or the Danube, and in North Africa, can the details of legionary camps and outposts of "auxiliary" troops be seen as parts of an orderly scheme of occupation; and as Mommsen himself admitted, "you have such wonderful inscriptions in your North country; no land tells us more about the Roman army."

Similarly, the "Romanisation" of Britain is a special and exceptionally interesting example of a process which was going on, during the same four centuries, in many border-lands. Here again geographical conditions impose rather austere control; all higher culture being "confined to a definite area in the centre, the east, and the south of the province. . . . Outside that area we may search practically in vain for traces of civilised life. Inside it we shall find almost nothing else," for when the military situation was once defined, troops were not stationed where they would be out of action in case of trouble on the border. There are qualifications to be made, of course; "in particular, the midlands were thinly and poorly peopled," yet in Cambridgeshire, as Dr. Cyril Fox has shown more recently, it was during the Roman occupation that we can first trace any serious exploitation of the forest-ridden clay-lands. There is a practical moral to this midland emptiness: "amidst its great woodlands, and on its damp and chilly soil, agriculture can expand only under the exceptional conditions of a Napoleonic war. Pigs, sheep and cattle may flourish better. . . ." So history repeats itself, and Roman Britain in its broad geographical features was very much the Britain that we know.

More important was the life of the towns; and though the first novelty of Haverfield's pioneer essay on

"Ancient Town-planning" is necessarily lacking here, the sections on the origin, structure, and outlay of Roman British settlements the adaptation of Roman architectural conventions to British weather and Celtic habits and the pottery and other characteristic elements in the furniture of the houses so developed receive much fresh illustration and commentary and no less perpetual challenge to traditional misconceptions whether the true story be available as yet or not

Especially is this suspension of judgment out of very fullness of knowledge apparent in the last of these lectures entitled Roman Britain and Saxon England and dealing with a state of things of which the writer frankly says that if for one reason it is not to be called a period for another reason it can hardly be called history Like the Bronze Age or the Early Iron Age it lies outside the ordinary range of historians

The early history of the English has been written often enough But it is mostly fiction The Celtic world is equally unhelpful I do not think I have exaggerated the general uncertainty which overhangs large parts of Celtic studies Here assuredly is no place for a respectable historian In Roman Britain on the other hand even for so severe a sceptic ancient history comes to the rescue of modern archæological detail purging the rhetoric and errors of Gildas But legend is history personified in fiction When we can test legends the general history proves usually to be true The heroic age remains—without the heroes The struggle between Roman British culture and Saxon barbarism was on a small scale truly compared with the great continental movements of that age but it was evenly balanced and fiercely disputed

Here archæology confirms legend utterly The conquerors were destroyers No case is known where Saxons dwelt in a Roman villa either by sack and burning or by evacuation the Roman towns ceased to exist as settlements as completely as those of the Danubian frontier of Noricum Geographical criticism comes to the rescue here too The Saxons advance 'went on to the same point as did Rome's and coots laid their eggs in the baths of Aquæ Sulis "Like Rome's it came to a stand at the foot of the hills" in more violent conflict with the Saxon Chronicle than with the surviving Britons But for the rest the Roman has passed from Britain as though he had never been. Once more, however this is the regional and, therewith, ephemeral view 'Had Rome failed to civilise, had the civilised life found no period in which to grow firm and tenacious, civilisation would have perished utterly But geographically Britain is an over-straits counterpart of what then was Gaul while Britain became England, Gaul became France, and in the longer story of the Romanisation of the Frank and through him of Saxon and Angle over straits we have the link which makes the history of Roman Britain a chapter consecutive with our own

(2) That a book like Mr Home's Roman York should find a public or a publisher at all is testimony to the real and wide interest in Roman studies to which allusion has already been made When we consider as the author notes in his preface that the total number of original references to York in extant Latin literature is five and that the remainder of its history must be reconstructed like a mosaic from indirect references and inferences in the light of epigraphic and archæological evidence we realise the amount of laborious compilation which goes to a book of more than two hundred pages It is indeed at the same time rather more than a history of Roman York and a good deal less than a survey of Roman Britain but the preface disarms criticism of its discursiveness and indeed Mr Home has only applied to a particular site the method of illustration from other places and districts which gives their value to the Ford lectures

Mr Home however is evidently not a trained scholar his Greek and occasionally even his Latin needs revision his references are few usually without chapter and verse in a note on p 59 all three titles refer to the same document! His English equivalents for Roman official titles are not always happily chosen his account of the status of *municipium* and *colonia* is obscure and he refers on p 76 to Huns in connexion with the events of A D 284 But he evidently knows York and its neighbourhood intimately he has had the valuable help of Dr Collinge Mr Foord and other local colleagues he writes vigorously and easily with a certain touch of imagination which gives coherence to a needlessly large mass of detailed information and he has illustrated his book with a number of excellent photographs He does not often mention Haverfield's work and occasionally falls foul of his opinions but knowingly or not he has learned in his school and his essay is living testimony to that revolution in method of which the Ford lectures are an epitome

Astrophysics without Mathematics

Modern Astrophysics By Prof Herbert Dingle Pp xxviii+420+46 plates (London and Glasgow W Collins Sons and Co Ltd 1924) 30*s* net

THE science of astrophysics has long since attained its majority It no longer needs the protecting presence of some more ancient science But it is at present almost devoid (at least in the English language) of that ordinary possession of a science—a literature It needs its classics its authoritative treatises its workaday text books its popular expositions, its

works of compilation and its works of criticism, its manuals of theory and its manuals of practice

Prof Dingle s Modern Astrophysics is a pioneer attempt at a popular exposition of the subject As stated in the preface the book is intended for the general public and the popular appeal has been given first place It is also comprehensive Its aim is to put a reader without specialised knowledge—either of physics astronomy or mathematics—in possession of the main range of facts of observation and of the theories propounded to explain them

It may be said at once that not only is there no book in English whi h even attempts this but also that Prof Dingle s book does in some measure achieve its aim The demands on the non technical reader are probably greater than the author supposes but he who is prepared to face four hundred pages of somewhat amorphous prose is conducted twice round the whole existing observational material is taken to some of the bounds of existing knowledge and is invited to peer into the recesses of the unknown The author con scientiously faces what h e considers to be difficulties and the book abounds in independent criticism though not all of it is wise The popular reader will however feel that the greatest respect has been paid to his intelligence and that he has been brought to the point at which he can at least frame sensible speculations of h s own

In collecting and arranging the facts Prof Dingle has expended a great deal of labour—labour which will make easier the future tasks of others For he has at least got the subject into a whole though rather a shapeless one In this connexion it may be regretted that references are almost non existent If these had been given even only for the tables the professional reader would have been greatly helped and the non professional one would not have been unduly terrified

The book would have been improved if the frequent dramatic and rhetori al passages had been omitted for they do not succeed in stimulating the reader s emotions more than would simple narration The author says that lack of space has compelled him to be brief This shows want of self criticism The book suffers from diffuseness Repeatedly loss of clarity arises from excess of explanation Though possessing the literary form of a popular work it has the dimensions and price of a treatise and if it had been reduced by one third and better provided with sub headings it would have been more readable and nothing of value need have been omitted

When one of the objects of the book is to give non mathematical explanations it is disappointing to find how often opportunities have been missed It is possible to show very simply in words, how the angular diameter of a star is connected with its surface brightness, how observations of eclipsing binaries yield determinations of stellar densities, and how the detection of a moving cluster plus a single determination of radial velocity affords good determinations of parallax These are three simple fundamental relationships Yet in Prof. Dingle s text the first is confused with the irrelevant introduction of parallaxes and the linear diameters of stars the second is stated but not argued out at all and the third is omitted save for a reference to the fact that if the parallax of one star of a moving cluster can be found those of the remainder follow from the common velocity Similarly no attempt is made to show why the period of a Cepheid should be expected to decrease with increasing density

This is the more to be regretted in that occasionally the author conveys much in little in an illuminating epigram for example when he remarks that though novæ have been classed as variable stars it is doubtful if such a classification expresses anything more than the philosophical instinct which craves after generalisation or again referring to the maintenance of energy evidently one of the star s most important functions the expression of its instinct for self preservation And such a sentence as A variable star is not the opposite of a fixed star is a charming example of tenderness for the difficulties of non professional brethren

Serious criticism can be made of the actual substance of parts of the book for example the chapter on the sun contains a long description of the rival theories of the gaseous photosphere and the cloudy photosphere, and the author gives the impression and evidently himself believes that there is little to choose between them Surely this is to speak the language of a previous decade It may be regarded as completely certain, and is believed on reasoned grounds by the overwhelming majority of astrophysicists that the photosphere does not consist of opaque incandescent clouds The author largely ignores the accepted results of mathematical investigations whilst attempting to traverse the same ground verbally for example the difficulty that has usually been encountered as soon as we leave the primrose path of verbal argument and introduce a few numerical estimates of orders of magnitude is that the sun s boundary ought to be more sharp than it is not less sharp

Again in dealing with the interior of a star the author shows how radiation is handed on from layer to layer and gives an indication of how the effect has been calculated by Eddington But in dealing with the sun he remarks how the energy distribution would be related to the huge range of temperature from the sun s centre to its surface is indeed a difficult problem It may be doubted whether the relation

would have much analogy with that observed when an isothermal surface is the radiator" This is not the only failure on the part of the author to assimilate different researches Though there is an introductory section on the theory of spectra, much of the book is written in the language of the era before a theory of spectra existed It would surely be easier for the ordinary reader to understand resonance radiation and fluorescent radiation rather than to be mystified by "non-temperature" radiation Referring to Wolf Rayet stars, Prof Dingle says 'The Wolf Rayet stars seem to be the only ones that behave as a wholly gaseous mass should Their spectra are intelligible—a faint continuous spectrum due to the light from the high-pressure interior which has managed to escape, with a bright line spectrum from the surface layers impressed on it" Prof Dingle is entitled to state his intuitive expectations, but he is not entitled to ignore the fact that mathematical analysis shows that a star is to be expected to give an *absorption* spectrum, the difficulty is to explain the existence of bright lines On another page, however, he remarks that Wolf Rayet radiation in general is inexplicable" His attempted explanation of a bright line spectrum—that when a star reaches its maximum temperature its central parts are cooling whilst the outer ones are getting hotter—is inadmissible, as a simple calculation shows

The author suggests that the hypothesis of the synthesis of helium from hydrogen is in keeping with the observed fact that the second spectrum of a nova has weaker hydrogen lines and stronger helium lines He apparently fails to realise the exceedingly small mass of gas required to produce even intense lines, an amount utterly negligible compared with the amount either of hydrogen or helium probably available

Prof Dingle says that, as we do not know the precise conditions inside a cooled star, we are at liberty to make any assumption that is not inconsistent with the little we do know He then says that [illegible] nebulæ may arise from a catastrophic outburst in [illegible]led star, for "we cannot say this is impossible so long as the heat energy inside the star is sufficient to account for the gravitational potential energy of the nebula, and there is every reason to believe it is sufficient' But why this meticulous respect for the first law of thermodynamics when the second law is being thrown overboard? It is simply not fair to the non-technical reader to make unorthodox suggestions of this kind without fully pointing out the nature of their unorthodoxy

The looseness shown by these examples is unfortunately present in much of the reasoning Astrophysicists will use the book for its summaries of facts, but they will be little helped by its theoretical discussions

E. A. M.

Blood Pressure in Early Life.

Department of Applied Statistics University of London, University College Drapers' Company Research Memoirs Studies in National Deterioration, XI Blood Pressure in Early Life a Statistical Study By Dr Percy Stocks, assisted by M Noel Karn Pp iii+88 (London Cambridge University Press, 1924) 12s net

DR PERCY STOCKS work entitled 'Blood Pressure in Early Life" immediately strikes one as filling a long experienced gap in medical literature Systolic and diastolic blood pressures are, indeed, taken to-day almost as a routine in the medical examination of a patient, and yet it is notorious how hazy are the conceptions of the normal range of these at different ages Especially is this the case in childhood and adolescence The principal aims of the author, therefore, were to investigate the behaviour of blood pressure during the period of puberty and adolescence, to ascertain the normal range of systolic, diastolic, and pulse pressures at ages from 5 to 40, and to examine the interrelation between these pressures and their correlation with pulse rate, physical development, muscular strength, respiratory and psychological factors, social class and athletic habits of life

The study, which is a statistical one, has brought out some extraordinarily interesting results, a few only of which we shall be able to mention The systolic pressure is found to rise as a simple function of age from 5 to 11 years The onset of puberty causes a well marked accentuation in the gradient until at the age of 19 a maximum of 130 mm of mercury is reached From 19 to 40 years of age no further change is detectable The comparatively rapid rise in systolic blood pressure during puberty is shown to occur even when the figures are corrected for body weight, which itself is positively correlated with blood pressure The diastolic pressure, on the other hand, shows an interesting divergence from the course of the systolic pressure in its rate of rise with age In this case puberty at first hinders the rise, but this delay is followed at the age of 18 by a rapid rise to a maximum during the 21st year Following this the diastolic pressure tends to fall somewhat up to the 37th year

It is evident from the age curves of systolic and diastolic pressures that the pulse pressure increases rapidly at the onset of puberty to reach a maximum about the age of 18, after which it decreases equally rapidly into the 21st year, afterwards increasing again as a simple function of age

These are some of the facts elicited by this statistical study Their explanation is, however, difficult Dr

Stocks incriminates the endocrine glands in the causation of the rapid rise in systolic pressure during adolescence. Experimental evidence, however, is against any pressor action by the sexual hormones, although the possibility of the suprarenal and pituitary bodies being in part or in whole responsible for this change cannot be excluded.

The product of pulse pressure and pulse rate is found to show a well-defined maximum during adolescence, the curve representing this product plotted against age showing a superficial resemblance to that of rate of growth in body weight The author tentatively agrees to the contention that this product is "an index of cardiac energy expended per minute in maintaining the circulation," and even gives this contention the dignity of an algebraic notation. We would point out that the static factor in the total energy expenditure of the heart per minute is proportional to the product of the minute output and the mean blood pressure during the ejection phase of cardiac systole, and is in no direct manner connected with the pulse pressure. Indeed, the fallacy of Erlanger and Hooker's suggestion was conclusively demonstrated by Miss Skelton, who found that the relation between the pulse-pressure pulse-rate product and cardiac output in the isolated mammalian heart varied enormously, in one experiment between 7 to 1 and 47 to 1

Again, in adults, assuming that the average output per beat remains fairly constant up to middle life, and assuming that the pulse-pressure pulse-rate product is an index of the energy expended by the heart per minute, the author draws the conclusion that the mean product of pulse rate and pulse pressure is directly proportional to the mean work done by the heart per minute, which is merely one of the author's original assumptions. Figures calculated on the further assumption, that the mean output per beat in large groups of growing individuals is proportional to the mean body weight of these groups, show that if the assumptions are justified one "must conclude that, when the age of 16 has been reached, the average heart is performing as much as or more gross work per minute than in adult life, in spite of the fact that it has presumably not attained full size."

Thus many of the conclusions of the author are based on the assumption that the pulse-pressure pulse-rate product is an index of the work done by the heart. We repeat that the experimental evidence strongly militates against the validity of this assumption. This, of course, merely throws doubt on the interpretation of Dr. Stocks' statistical figures. The results obtained are of absorbing interest and undoubtedly will be of great value to medical officers of schools and of insurance companies.

Our Bookshelf.

The Physiology of Photosynthesis. By Sir Jagadis Chunder Bose. Pp. xx + 287. (London: Longmans, Green and Co., 1924.) 16s. net.

LIKE all the monographs from the Bose Research Institute, this book contains an account of new and very ingenious experimental methods, and a discussion of experimental results, so detached from the general current of plant physiological literature that it becomes difficult, if not impossible, to assimilate the new data into the fabric of the science. Practically all experimental work is carried out upon the water plant *Hydrilla verticillata*, a most ingenious bubbling method being used to record the rate at which oxygen is released during photosynthesis

The presence of nitrogen in the gas expelled from the plant is prevented by supplying the plant with water free from nitrogen, but where experiments are being carried out in varying concentration of carbon dioxide, the earlier work of Devaux on the intercellular atmosphere of water plants suggests caution in the interpretation of experimental data This method, however, rendered automatic by an electromagnetic device registering on a recording drum, should prove of very great value and have many applications.

Two other methods are also used; in one the rate of oxygen discharge is recorded by the change of buoyancy in a submerged shoot attached to a torsion balance; in the other the bubbles are removed by raising the shoot out of water and then measuring afterwards, either in a torsion balance or a precision chemical balance, the change in *density* of the submerged shoot due to the accumulation of assimilates which are assumed to be carbohydrates. Osmotic and turgor charges with their consequent effects upon the volume of the intercellular air system are apparently disregarded in this method.

As to experimental results, Prof. Bose has previously briefly reported in NATURE (July 21, 1923) the great sensitiveness of the process of photosynthesis to certain substances, as, for example, to the slight amount of nitric acid carried down into the ponds after thunderstorms. Many of his more general conclusions will probably not attract so much attention as the new experimental methods he has employed.

The Cultivation of New Zealand Plants. By Dr. L. Cockayne. (New Zealand Practical Handbooks.) Pp 139 + 21 plates. (Auckland, Christchurch, Dunedin, Wellington, Melbourne, and London: Whitcombe and Tombs, Ltd., n.d.) 4s. 6d.

DR. COCKAYNE deserves the thanks of those interested in horticulture, both in New Zealand and in the British Isles, for his excellent practical book on New Zealand plants. It is of particular value for plant lovers in New Zealand, since he brings to their notice the many remarkable native plants which gardeners are so apt to neglect. It is too often the case abroad to find that residents, who may have come from the Home Country, desire only to grow those plants they have known at home, and often neglect almost entirely the native plants of their country of adoption. Similarly, in Botanic Gardens in the Colonies, it is common to find the native flora very largely neglected and mainly a

fine collection of exotic plants under cultivation From Dr Cockayne's book it is clear that in the New Zealand Botanic Gardens, care is taken to cultivate as representative a collection of the native plants as may be possible, and the efforts which have been made in this direction are worthy of the highest praise

Now, thanks to Dr Cockayne the same aim is made possible and easy to all lovers of gardens in New Zealand as he gives full particulars as to how the plants should be procured and cultivated and then goes on to give lists with good descriptive accounts and methods of propagation of the native trees shrubs Veronicas herbs, climbing plants, and ferns suitable for gardens There is also an interesting and very useful chapter on native plants suitable for town gardening The book is well illustrated with a number of excellent plates and is also furnished with a map and full index

Das Wildseemoor bei Kaltenbronn im Schwarzwald ein Naturschutzgebiet Von Dr Karl Müller Pp vi +161+19 Tafeln (Karlsruhe i B G Braun G m b H 1924) 3 marks

The author spent thirteen years in the study of a particular piece of moorland vegetation in the vicinity of Baden Baden The area is noted for its beauty and Dr Müller loves the region—a fact that contributes largely to the fascination of the book But not only is the Wildsee a lovely spot it is also of peculiar interest to the student of natural history In his preface the author states that the fauna and flora of the moor is that of the arctic alpine type comparable to an island in the midst of a sea of central European forest produced by the ecological singularity of its position Beginning with the history of the moor from the eighteenth century, he traces its life from 1780 when its water supply was originally tapped Later the peat itself was exploited During these periods the drained areas were utilised for afforestation schemes with conspicuous failure—sphagnum growing most freely on those areas from which the peat had been taken and reconverting them into bogs Since the Armistice the author's knowledge of the region and his numerous articles upon it have assisted in the postponement of further projects to use the peat and we are glad to learn that this beauty spot will be converted into a national preserve The book is well illustrated with photographs and maps but unfortunately it does not possess an index though it has a good table of contents It will appeal to all lovers of Nature and to students of ecology, for it contains much useful material attractively arranged regarding moorland vegetation It was written originally to interest all who know and love this beautiful part of the Black Forest.

Lectures on the History of Physiology during the Sixteenth, Seventeenth and Eighteenth Centuries By Sir Michael Foster Second impression Pp vii+306 (Cambridge At the University Press, 1924) 15*s* net

The history of the development of medicine has been told many times, but rarely can we gather from these accounts a clear history of the two subjects, anatomy and physiology, on which the whole structure of the art of healing is built The late Sir Michael Foster's book consists of the "Lane Lectures" delivered at the Cooper Medical College in San Francisco in the year 1900, and gives a detailed narrative of the progress of physiology in the sixteenth, seventeenth and eighteenth centuries In one important detail it differs from many books of its type it is the history of the science not merely of the lives of scientific workers Yet there is included much about the personal histories of the pioneers of physiology which stimulates additional interest in the fruits of their labours The author sees in the efforts of Vesalius against the blind dogma of the Middle Ages the foundations of modern physiology and modern anatomy Harvey's great work he regards as the direct outcome of those efforts The influence of advancing knowledge of physics and chemistry is demonstrated in the ideas of Borelli Paracelsus and Franciscus Sylvius In Mayow's realisation of the functions of what is now called oxygen there is an illustration of how a great scientific discovery may be completely ignored in its time and find recognition after more than a century

The value of this book may be indicated by quoting the author's own words It is one of the lessons of the history of science that each age steps on the shoulders of the ages which have gone before The student will find in the book an account of this progression which will enable him better to understand the physiology of his own age

Antiques their Restoration and Preservation By A Lucas Pp viii+136 (London E Arnold and Co 1924) 6*s* net

Mr Lucas's book forms a very useful introduction to the modern methods of treatment of antiques on which subject very little literature has hitherto been available, but being written in as non technical a manner as possible it is likely to be of more value to the antiquarian than to the chemist

The work is divided into four chapters the first two giving a general outline of methods of treatment while the third is devoted to their application to specific materials A short final chapter gives certain simple tests for determining the composition of objects

While the majority of the methods recommended in the third chapter have been found to be safe yet certain of the author's methods would be dangerous in inexperienced hands For example the treatment of papyrus by soaking in water is somewhat drastic Papyrus which is composed of small sheets stuck together is very liable to disintegrate under treatment, and it is safer to cover it with moist blotting paper But in most cases the author has confined himself to describing methods of proved utility which provided the fragility of antique objects is borne in mind can be used by any one He is however, rather unduly fond of the use of paraffin wax to which cellulose acetate is usually to be preferred

Some of the tests given in the fourth chapter may be misleading to those ignorant of science The methods given for determining specific gravity are likely to be very inaccurate Since the object must in any case be weighed in air, it would be better to instruct the reader how to weigh it in water, for only thus can an opinion be formed as to the genuineness of, for example, a coin But these are comparatively small faults in a book which all antiquarians will be well advised to study R A M

On the Luminescence of Solid Nitrogen and Argon.

A LETTER in NATURE of November 15, by Prof. L. Vegard, contained some statements regarding the work of Dr. Shrum and myself on the luminescence of solid nitrogen and argon that would appear to warrant some comment from me. Prof. Vegard's article appears to give the impression that our discovery that the band near $\lambda = 5577$ Å in the spectrum obtained with solid nitrogen had a triplet structure with none of the components coinciding with $\lambda = 5577{\cdot}35$ Å was made after he himself had noted this fact. A reference to our paper will show that it was received by the Royal Society on June 14 of this year. A brief notice of it appeared in NATURE of July 5.

Although we had found late in January 1924, or early in February, that this band, now called N_1 by Prof. Vegard, had a triplet structure, we withheld publication of that fact until a paper by Prof. Vegard should appear, because we inferred from reports appearing in the daily press about that time that he had found the auroral "green line" in the spectrum of solid nitrogen bombarded by electrons.

As no reference to the triplet structure of the N_1 band was made in Prof. Vegard's paper that appeared in *Comptes rendus* of March 31, or in that published in the issue of NATURE for May 17, we communicated our paper to the Royal Society on June 14. On June 17 Prof. Keesom communicated to the International Congress on Refrigeration a paper by Prof. Vegard summarising the latter's work, and dated May 13, with an appendix dated May 31, and a further one dated June 13. In this paper, and in its appendices, again no reference was made by Prof. Vegard to the structural character of the N_1 band.

At the conclusion of the presentation of Prof. Vegard's paper at the Congress of Refrigeration, I was permitted to show our photographs of the solid nitrogen spectrum in which the structure of the N_1 band was revealed. In a paper in *Comptes rendus* of July 7, Prof. Vegard referred for the first time to the fact that the N_1 band had a triplet structure. This paper, therefore, confirmed our results, although no mention was made in it of our work, which was known to Prof. Keesom and others from the Leyden laboratory, on June 17. Again, in a later paper in *Comptes rendus*, July 21, Prof. Vegard dealt with the subject, but again made no reference to our work. It is not conceivable that Prof. Vegard observed prior to June 13 that the N_1 band had a triplet structure with none of the components coinciding with the auroral green line, and withheld that very important fact in the communications of his results obtained up to June 13.

Prof. Vegard suggests that differences between his observations and ours "may be partly due to the fact that their [McLennan and Shrum's] experimental material was very limited, and that their arrangements made it difficult to overlook the experimental conditions and to vary them in a known way." Prof. Vegard apparently is not familiar with the equipment available in the Physical Laboratory at Toronto for researches of this character. Many scientific workers who have visited our laboratory will be able to support me in the statement that our cryogenic and spectroscopic equipment is amply sufficient to meet far more exacting demands than those presented in this investigation. A casual glance at the reproductions of our photographs will show, too, that we were not ignorant of the best methods of using this equipment. Again, Prof. Vegard states that our difference of opinion does not originate from a difference with regard to experimental facts. If we, with our experimental arrangements, were able to obtain the same experimental facts as he did, then he can scarcely maintain that our experimental arrangements made it difficult to "overlook and vary the experimental conditions."

The experimental facts in so far as we know them are as follows:

We found that when solid nitrogen was bombarded with electrons, the luminescent band N_1 consisted of three "broad lines or narrow bands," with mean wave-lengths $\lambda = 5654$ Å, $\lambda = 5617$ Å, $\lambda = 5556$ Å. Prof. Vegard has found the same structure, but with the mean wave-lengths $\lambda = 5649$ Å, $\lambda = 5611$ Å, and $\lambda = 5555$ Å.

We found that solid nitrogen, when made to phosphoresce by electronic bombardment, gave a spectrum consisting in the visible region of a single broad line or narrow band at $\lambda = 5231$ Å. Prof. Vegard finds the wave-length of this narrow band to be $\lambda = 5229{\cdot}4$ Å.

We found that the spectrum of pure solid argon, when the latter was bombarded by electrons, contained a band consisting of two components, one of them being strong with a mean wave-length at $\lambda = 5607$ Å, the other faint with a mean wave-length at $\lambda = 5648{\cdot}3$ Å.

Prof. Vegard, when bombarding solid argon containing varying amounts of solid nitrogen with electrons, found a spectral band consisting of several components with the strongest member having a mean wave-length at $\lambda = 5604$ Å.

We found, when great precautions were taken to purify the argon we used, and only when such precautions were taken, that solid argon phosphoresced after bombardment by electrons, and that the phosphorescence spectrum of argon so treated consisted in the visible region of two broad lines or narrow bands at $\lambda = 4750$ Å and $\lambda = 5300$ Å. This phosphorescence spectrum of solid argon Prof. Vegard does not appear to have observed as yet.

Prof. Vegard takes the view that the results of his solid nitrogen-argon experiments indicated the oscillation of the principal maximum in the N_1 band between $\lambda = 5555$ Å and $\lambda = 5604$ Å.

We feel inclined, however, to the opinion that his results in this connexion indicate that he obtained a mixture of the N_1 components of the nitrogen band and of those of the argon luminescence band in the same region. It may be added that, in our experiments, we found the positions of the components of the N_1 nitrogen band, as well as that of the N_2 phosphorescence band, the same with the solid nitrogen at the temperature of liquid helium as at the temperature of liquid hydrogen.

Our experiments, it may also be stated, did not preclude the possibility of the components of the N_1 nitrogen band originating in the cold vapour of nitrogen in contact with the solid nitrogen. Prof. Vegard is of the opinion that these component spectral bands originated in the solid nitrogen only. He concludes that if the particles of the bombarded solid nitrogen were gradually reduced to molecular dimensions, the N_1 composite band would degenerate finally into the very fine auroral line $\lambda = 5577{\cdot}35$ Å. It is difficult for me to follow him to this conclusion.

It seems to me that in an examination of the

validity of Prof. Vegard's theory, some useful information might be gained by directing more attention to the *phosphorescence* of solid nitrogen. Does the phosphorescent nitrogen band $\lambda = 5231$ Å appear in the spectrum of the aurora or not? If it can be shown that it does, we shall know that the region in which the auroral light originates is at or near the temperature of liquid hydrogen. If this line does not appear in the spectrum of the aurora, and if the temperature of the region in which the radiation constituting auroral spectra originates is at or near the temperature of liquid hydrogen, then why does the phosphorescence nitrogen spectral band not appear along with other nitrogen bands found in auroral spectra by Vegard, Rayleigh, and others?

From Kayser's "Handbuch" one finds that a line or narrow band has been found by different observers in the spectrum of the aurora with the following wave-lengths: $\lambda\lambda = 5269$ Å, 5205 Å, 5200 Å, 5233 Å, 5210 Å, 5239 Å, 5207 Å, 5228 Å, 5235 Å, 5166 Å, and 5230 Å, but the list of wave-lengths observed by Vegard in the auroral spectrum and given by him in his paper in the *Phil. Mag.* of July 1923 contains no wave-lengths between $\lambda = 4708{\cdot}7$ Å and $\lambda = 5578{\cdot}2$ Å. It appears, however, from a statement in one of his more recent papers, that he has observed in the spectrum of the aurora a trace of a line near $\lambda = 5230$ Å. Cario has found a band in the spectrum of oxygen near $\lambda = 5230$ Å, and Prof. A. Fowler recently pointed out to me that Ångström and Thalen found a negative band in the spectrum of nitrogen at $\lambda = 5227{\cdot}5$ Å. It seems very desirable, then, to repeat the observations on the auroral spectrum to see if there is any trace of a wave-length at or near $\lambda = 5231$ Å. If such a spectral line or band should be found, it would be well to have a very exact determination of the wave-length made in order to decide whether the corresponding radiation originates in nitrogen in the gaseous or solid state, or in some other element in one or other of its states.

It is unfortunate that Prof. Vegard's brilliant prediction has not as yet received experimental confirmation. It would appear that neither he nor we have as yet obtained with nitrogen or argon, or with mixtures of these two elements at the temperatures of liquid hydrogen or helium, by the use of any agent, a spectrum that includes a broad line or narrow band within a region of 10 Å on either side of the famous "green line," the wave-length of which, according to measurements made with great precision by Babcock, is $\lambda = 5577{\cdot}35$ Å. Nevertheless, Prof. Vegard's theory has been most stimulating, and has led already to the discovery of valuable and important experimental results.

University of Toronto, December 6.

The Life of Lord Rayleigh.

History should have as little fiction attached to it as possible and evidence should be tendered in time, by those who can speak with knowledge: this view may not be in accordance with practice, none the less, it may be advocated as desirable doctrine, especially as it has the authority of the author of *Zadig*—a saint recommended for worship by Huxley—who has said:

> On doit des égards aux vivants,
> On ne doit aux morts que la vérité.

All who knew the late Lord Rayleigh even distantly—he was very difficult of approach—will agree with Sir J. J. Thomson (Nature, December 6, p. 814) that his son has written his Life with remarkable skill and sense of proportion—but some of us can scarcely admit that nothing more is to be said even of the discovery of argon. The account given is only partial, in no way a complete presentation of the episode; among others, we should like to have heard the views of Gordon, the discoverer's devoted laboratory servitor. Lord Rayleigh was but young at the time of the achievement and cannot have been aware of the state of feeling among chemists—nor, probably, was his father; he will not know in what reverence we held his father's work. I suppose I was behind the scenes as much as anyone, the more as I was president of the Chemical Society, was thoroughly acquainted with Ramsay and his ways and, as is well known, an intimate friend of Sir James Dewar.

At the annual general meeting of the Chemical Society, on March 27, 1895, I made the following statement, to the fellows, in my address.

> Your Council have decided to appoint Lord Rayleigh our Faraday lecturer and to request his acceptance of the Medal in recognition of the important service which he has rendered to Chemistry by his discovery of Argon.

I handed the medal to him from the presidential chair—he accepted it. His guarded remarks in acknowledgment are on record in our Journal. The Chemical Society advisedly took the view that it was *his* discovery. There was the strongest possible feeling among chemists that his name alone should have been associated with the discovery. I may add that, on the same occasion, I had the pleasure of calling upon Ramsay to make public his startling discovery of helium in cleveite, which was thereupon confirmed by Crookes.

Lord Rayleigh has dealt mainly with his father's electrical work (on the ohm and the ampere) and that on argon. Probably some of his readers are disappointed that he did not also summarise his activity in other directions—particularly his work on oil films and capillarity, which is proving to be of special interest and importance in our field. If I be not mistaken, the part he took in such inquiry is not sufficiently recognised. If another edition be called for, let us hope that a chapter on his work in general will be added.

As to my friend Sir Joseph Thomson's gibe at chemistry—what is chemistry? I hold that chemistry and physics are inseparable disciplines, the parting line a broad valley through which both flow; the pity is that physicists so rarely stray from their own region up the chemical slope, that their vision is so little adjusted to our country. They suffer, indeed, from *Chemo-myopia*, not *Chemotaxia*, I fear the fault is congenital. Apart from Regnault and Rayleigh, I believe determinations of the density of gases are all but entirely the work of chemists—has not Sir Joseph heard of Avogadro's theorem and of one Cannizzaro, a chemist and Roman Senator? The determination of gaseous density is *the* fundamental operation in chemistry, as he will see if he consult a bygone classic, Cooke's "New Chemistry". Gaseous density is the foundation stone of our entire numerical system. What, however, can they know of chemistry who only physics know? Indeed, there would seem to be a constitutional aversion from our science in the mind of the physicist—he lacks the necessary freedom of outlook to appreciate our numberless excursions. The slowness with which Lord Rayleigh saw the treasure beneath his feet was probably owing to the fact that he had little real chemical feeling; Ramsay at once appreciated the value of the find when asked to inspect the ground and took shares without hesitation.

The Adhesive Apparatus of the "Sucking-fish."

EARLY in 1923 I published in NATURE a short summary of my views regarding the mechanism of the so-called suckers of certain hill-stream fishes and of the "Sucking-fish"—Echeneis.[1] My conclusions were based on an examination of the living specimens of two Indian genera of hill-stream fishes —Pseudecheneis and Glyptothorax, and on a study of preserved material of Echeneis. Later, at my request, Major R. B. Seymour Sewell, Surgeon-Naturalist to the Marine Survey of India, very kindly performed a series of experiments on living specimens of Echeneis. Quite recently (September 1924) I have been able to conduct a few experiments on the "Sucking-fish" in the Marine Aquarium at Madras. In carrying out these experiments I received great help from Dr. Sundara Raj, acting director of the Madras Fisheries, and Prof. H. Parameswaran, of the Presidency College.

The following experiments were carried out to test the sucker-theory of the disc of Echeneis —

A smooth tin sheet perforated all over with minute holes was taken, and the fish was allowed to attach itself to it. It was observed that the animal was not able to stick to such a surface. This experiment was repeated with a piece of fine-meshed wire gauze in place of the tin sheet with similar results. A wooden plank with a large number of parallel grooves running across it at short distances was next used in place of the wire gauze. The fish could not adhere to such a surface.

In all these experiments it was observed that the fish did not like to have its sucker placed against either very rough or perforated surfaces. Moreover, on such surfaces it secreted large quantities of mucus from its disc. In all probability this secretion helps the fish in sticking to rough surfaces.

The fish was next allowed to adhere firmly to a smooth sheet of glass or a tin sheet. It was found that on such smooth surfaces the fish could be made to slide forwards and sideways without any difficulty, but a certain amount of force was needed to pull it backwards or vertically upwards. When pulled vertically upwards, the resistance against the pull is due to the sucker formed by the disc; while the force resisting the pull in the backward direction is due to the mechanical frictional device formed by the innumerable backwardly directed spines on the lamellæ of the disc. When lifting the fish vertically upwards it was observed that the entire outer rim of the disc formed a big sucker. In the next experiment the formation of the sucker by the entire rim of the disc was rendered impossible by introducing a number of match sticks under the rim. It was then discovered that a double series of secondary suckers were also formed between the transverse lamellæ on the two sides of the central axis of the disc. This was confirmed by gradually lifting the disc from behind, when it was noticed that each secondary sucker gave way with a hissing sound. It may also be noted that the secondary suckers produced between the lamellæ are not only independent of the outer large sucker, but are also independent of each other.

The disc of Echeneis, when in action, is therefore composed of an outer sucker formed by the rim, and of the two rows of secondary suckers formed in the grooves on either side of the central axis. At the same time, the spines on the lamellæ prevent the fish from slipping off whenever the animal is pushed backwards. The usefulness of the spines for attachment comes into play when the "Sucking-fish" is adhering to such fast-swimming animals as sharks and whales.

The case of the hill-stream fishes is somewhat different. They have only to contend against a rapid-running current constantly flowing in one direction. Suckers under such conditions are probably less useful than non-slipping frictional devices. This is beautifully illustrated by the various Indian species of the genus Garra.[2] In species of the genus which live in lakes and comparatively still water (*e.g. G. mullya, G. gravelyi*), the mental disc is large, and the adhesive pads on the under surface of the paired fins are feebly developed, while in species which inhabit rapid-running streams (*e.g. G. kempi, G. gotyla*) the disc on the under surface of the head is somewhat reduced and the non-slipping adhesive apparatus on the under surface of the paired fins is well developed. The frictional device in the case of these fishes is more useful than a vacuum sucker. The strength of a vacuum sucker is limited according to its area, while friction increases with pressure, and this in hill-streams increases with the rapidity of the current. The similarity in shape between the anterior dorsal profile of the hill-stream fishes and the anterior ventral profile of Echeneis shows similarity of purpose, which is to utilise the force of the current for increasing the pressure on the disc and thus to make it stick more firmly to the substratum.

SUNDER LAL HORA.

Indian Museum, Calcutta,
November 4.

[1] Hora, NATURE, 111, p. 668 (May 19, 1923). See also Rec. Ind. Mus. 25, pp. 587-591 (1923).

IN order to test the action and mechanism of the disc in Echeneis and determine whether or not one function of the disc is to act as a sucker (in the strict sense of the word) a series of experiments were carried out.

Specimens were allowed to attach themselves to clean sheets of glass, and the disc was then examined and compared with the surface of the disc when unattached. In the unattached state the rim of the disc is soft and flexible, and around the anterior half of the disc the margin is distinctly raised while the posterior half is flat, the transverse ridges, on which are numerous posteriorly-directed spines, lie flat against each other and present a practically continuous surface. When the animal has attached itself by the disc, the smooth flexible margin can be seen to be closely pressed against the glass. The ridges running transversely are now separated from each other by narrow spaces, the two series, *i.e.* right and left, being separated by a median soft band that passes backwards in the middle line. At the posterior end this ridge stops short, so that the terminal posterior part of the sucker is occupied by a single large cavity the floor of which is depressed. Air bubbles can be seen between the ridges and in this posterior chamber, and such bubbles may be seen passing along each side of the median partition into the posterior chamber.

When thus attached, if the posterior rim of the sucker is separated from the glass, air immediately enters the posterior chamber, and by slowly pulling the sucker away, each pair of spaces between the transverse ridges can be opened separately, each giving way with a slight sucking noise; each compartment of the disc thus appears to act as a separate sucker.

When once the fish has attached itself by the disc it can be moved forwards or sideways easily, the disc sliding over the plate, but on attempting to pull the

[2] Hora, Rec. Ind. Mus. 22, pp. 533-587, pls. xxiv.-xxvi. (1925).

fish backwards, the spines on the ridges of the disc come into action and tend to prevent any backward movement; and if the disc is forcibly pulled backwards the spines can be heard scraping over the surface. If pieces of twine are placed across the disc they prevent the formation of the necessary partial vacuum and the disc fails to adhere, while if the disc is adherent, the introduction of a finger-nail or the blade of a knife between the disc and the surface to which it is adhering allows air to enter and the hold of the sucker is immediately destroyed.

Further experiments were conducted in order to try to determine the strength of adherence of the sucker. In the first experiment, an Echeneis was allowed to attach itself to the enamel surface of a dish and a hook attached to a spring balance was passed through the gill from one side to the other. By standing on the dish and pulling on the spring balance, the amount of force could be fairly accurately measured, and in the specimen experimented with the fish withstood a vertical pull of more than 30 lb. before the hook tore through the tissues of the body. Further experiments were conducted by allowing the fish to attach itself to an enamel iron tray, the tray being fastened securely by rope to the spring balance. The balance was attached to a stanchion, and the head of the fish was seized in a towel to prevent the fingers from slipping on the skin of the fish. Two examples withstood a vertical pull of 34 and 35 lb. respectively before the sucker was pulled away from the surface.

It seems to me that there is little doubt that the disc acts as a true sucker by the creation of a partial vacuum, while the spines are of use in preventing this sucker from sliding on the surface of attachment. Thus, during life, when the Echeneis attaches itself to some other larger fish, it is owing to the partial vacuum formed that the disc adheres to the surface, while the spines prevent the Echeneis from being swept backwards by the rush as the large fish makes its way through the water.

A further point worth noting is that when the sucker is in action and the Echeneis is attached to any object, all movement of the fish, except that of the mouth and gills that is necessary for respiration, seems to be suspended and inhibited. The fish hangs absolutely motionless, and in the case of a fish that had been well hooked, it was found that by allowing the fish to attach itself to a glass plate it would hang motionless, while the hook and a great part of the fish's jaw was cut out! It appears that the action of the sucker causes inhibition of all movement of the body and tail.

In order to avoid any misapprehension, may I be allowed to add that my experiments were carried out at the suggestion of Dr. Hora, and the above notes, recording the results, were forwarded to him last January.

R.I.M.S. *Investigator.*

Transmission of Stimuli in Plants.

AN article appears on the above subject in NATURE of October 25, in which reference is made to Mr. Snow's experiments (Proc. Roy. Soc., Series B, Vol. 96, No. 678) in support of Ricca's theory that conduction of stimulus in Mimosa is brought about by the transpiration-current in the wood carrying a hypothetical stimulating substance. Mr. Snow joins two cut pieces of stem of *Mimosa pudica* by a tube filled with water and applies a flame to the lower half of the stem with the result that the leaves of the upper half of the stem undergo a fall, hence it is concluded that stimulus is conducted across the water-gap. Mr. Snow also finds that the transpiration-current in Mimosa travels at about the same rate as the conducted excitation. I have carried out numerous experiments with this plant relating to the supposed transmission across a water column, taking the precaution that the heated air from the flame did not excite the upper leaves. Other modes of stimulation were also used which were less open to sources of error. In no case did I find any evidence of the transmission of stimulus through the tube filled with water. This is confirmed by the results obtained by Prof. Koketsu last year, who found that when the petiole of Mimosa was cut into two halves, and rejoined by a water-tight tube filled with water, stimulus applied on the distal half was never conducted across the gap. (R. Koketsu, Journal of Department of Agriculture, Kyushu Imperial University, Vol. 1, p. 55, 1923.)

I also applied a chemical stimulant, and made a simultaneous determination of the rate of the transmitted excitation and of the rate of transport of the stimulating substance. The two rates are of very different order, that of the transmission of excitation being at least a hundred times the quicker. The slow transport of a stimulant or of a hormone, and the rapid transmission of excitation, ought not to be confused with each other. I have carried out numerous experiments which prove conclusively that the transpiration-current has nothing to do with the conduction of the excitatory impulse.

In the article referred to above, I find no reference to my earlier researches on the transmission of excitation in Mimosa, some of which were published so far back as eighteen years ago ("Plant Response," 1906, "An Automatic Method for the Investigation of Velocity of Transmission of Excitation in *Mimosa*," Phil. Trans., 204, B, 1913, "Irritability of Plants," 1913, "The Dia-heliotropic attitude of Leaves as determined by Transmitted Nervous Excitation," Proc. Roy. Soc., B, Vol. 93, 1922). These researches proved conclusively that the *conduction is a phenomenon of propagation of protoplasmic excitation*. This was proved by numerous experiments of a crucial character. Among these may be mentioned the characteristic polar effect of a constant current in protoplasmic excitation. I have shown that an excitatory impulse is initiated at the cathode at "make" and at the anode at "break" of the current, the excitatory impulse being afterwards transmitted to a distance. I have shown, moreover, that the interposition of an electrotonic block arrests the excitatory impulse in the conducting tissue of the plant as in the nerve of the animal. The above results have since been fully confirmed by Koketsu. The characteristic effects described above disprove the theory that the transpiration-current is concerned in the conduction of excitation. A full account of my more recent experiments will, I hope, be published shortly.

An Approximation to the Probability Integral.

REFERRING to Prof. H. C. Plummer's letter on "An Approximation to the Probability Integral," published in NATURE of October 25, the following alternative way of representing the normal error function by simple approximation may be of interest. The original demonstration of this has been given by me in Physical Department Paper No. 8, "A Method of Curve Fitting"

Let us write as follows the equations for the three variables x, y, z.

$$z = \frac{a}{\sigma\sqrt{2\pi}} e^{-x^2/2\sigma^2}, \qquad (1)$$

$$v = \int_0^x z\,dx. \qquad (2)$$

In the above-mentioned paper it is shown that the equation

$$z = k\left(\frac{a^2}{4} - v\right)^{0.8111} \qquad (3)^1$$

gives a very close approximation to the values taken from a Probability Integral Table. The numerical value of k may be computed from

$$k\sigma = \frac{1.2318}{a^{1.6222}} \qquad (4)$$

Now, eliminating z from equations (1) and (3)

$$v = \sqrt{\frac{a^2}{4}} - 10^u, \qquad (5a)$$

$$u = \log_{10}\frac{a^2}{4} - 0.2677\left(\frac{x}{\sigma}\right)^2 \qquad (5b)$$

Putting $a = 1000$, the following Table shows the degree of accuracy of the equations (3), (5), and of Prof. Plummer's formula.

From Prob. Integral Table		From (3)	From (5)	Plummer's
x	y	x	v	y
0.0	398.9	0	400.1	0	0
0.5	352.1	191.5	351.8	189.0	191.5
1.0	242.0	341.3	240.6	339.2	342.0
1.5	129.5	433.2	129.7	433.1	435.1
2.0	54.0	477.3	56.3	478.3	478.8
2.5	17.5	493.8	19.9	494.7	488.4
3.0	4.4	498.6	5.6	499.0	
3.5	0.9	499.8	1.3	499.9	

Prof. Plummer's formula may be used only up to $x/\sigma = \sqrt{6} = 2.449$ (see NATURE of October 25). It is simpler than equation (5), and is to be preferred whenever values of y are quickly wanted for small values of x. However, in practical statistical work, problems may arise requiring one of the variables x, y, z to be determined in terms of one of the other two over the whole of the range of x. For such cases, when great accuracy is not wanted, the above equations may be useful to replace Probability Integral Tables. The variable x may be computed in terms of y from equations (1) and (3).

The Word "Scientist" or its Substitute.

I DO not think exception can fairly be taken to the adoption into a living language of any word that (1) contributes to convenient expression and (2) violates no rule or custom in etymology. Contemporary speech has this advantage over a dead language as a vehicle of thought, that it can be adapted to changing circumstance, whether that be effected by modifying the meaning of old vocables or by the addition of new ones. The invention of printing did much to arrest colloquial change and to standardise speech, but a useful measure of elasticity still prevails. Examples in point are the verbs "to burke" and "to boycott," which it would be very inconvenient to discard.

It has been pointed out by correspondents in NATURE that there is plenty of analogy in sound English for the formation of "scientist" from "science". Sir E. Ray Lankester objects to the term because there is no precise definition of science, but surely we all know what is meant by a "man of science," for which term "scientist" seems a neat synonym, standing aptly in antithesis to "sciolist"—one who has a smattering of some branch of knowledge.

HERBERT MAXWELL.

Monreith, Whauphill,
Wigtownshire.

WRITING as a student of the history of words, "scientist" can never become a *permanent* part of any language, for its quantity is "impossible". It has a destructive effect in a sentence, and when spoken the last syllables must be gobbled. "Naturalist" may be gobbled fairly easily; few people notice it, but "scientist" is difficult. So perhaps it scarcely matters whether the word receives or not the approval of the dictionaries, words which we instinctively feel are repulsive drop out of use.

The only possible salvation for the word is for its advocates to introduce the more correct pronunciation "sciéntist," that is, middle syllable accented. Thesist, logist, are alternatives which suggest themselves; the latter would be in conformity with "biology" and the many other "logy's".

The Spectrohelioscope.

I AM very glad to learn from NATURE of November 8, p. 683, that Mr. F. Stanley is also engaged in developing a spectrohelioscope. In my long focus (13 feet) instrument, where the slits are rather narrow and hence close together in order to give sufficient light with the requisite purity, the motion of the spectral line is practically equal to that of the slit for the small displacements from the optical axis involved. Thus it is possible to avoid the use of such deflecting prisms and gearing as Mr. Stanley employs. I have not yet attempted, however, to design a short focus instrument.

A rotating disc with radial slits makes a natural appeal to the instrument designer and I used it for my first (unsuccessful) experiments, made on Mount Wilson with the 30-foot spectroscope of the 60-foot tower telescope many years ago. It will serve very well with a moderate number of slits when there is sufficient light, but the high purity required for observations of the hydrogen flocculi complicates the problem. For example, in order to obtain with a disc the purity and brightness I now command with an oscillating bar (carrying two sets of five slits each), it would be necessary to use about 400 radial slits, each 0.003 inch wide and with errors of spacing less than 0.001 inch. This can, of course, be done, and I shall probably try it, but the simple oscillating bar suggested itself as an easy means of making a rigorous test of the method for the exacting task of observing the hydrogen flocculi against the brilliant disc of the sun.

[1] The exponent of equation (3) has been previously given as = 0.7864 and has been recently corrected to 0.81111 by more rigorous methods. Equation (4) has been correspondingly corrected.

The Compton Effect.

APROPOS of the very readable review of the discussion on scattered X-rays at the Toronto meeting of the British Association, published in NATURE of October 25, p 627, we presume your readers may be interested in a bit of new evidence on the reality of the Compton effect, obtained since that meeting.

We have photographed spectra of scattered molybdenum rays, with the tube and scatterer in one room and the spectrograph in another. The walls near the tube and scatterer were lined with lead, and the room was large enough to remove all other substances exposed to the rays to a safe distance. By that we mean a distance such that even if those substances converted all the radiant energy falling on them into tertiary rays, the total quantity of tertiary radiation sent by them to the "scatterer" would be reduced by the inverse square law alone far beyond detection. We built two such sets of apparatus, in different parts of the room, and used them at different times. One was a molybdenum-target tube with a sulphur scatterer The other was another molybdenum-target tube, of a different form, with an aluminum scatterer, using a spectrograph of quite a different design

Both of these sets of apparatus gave spectra like those described previously by Ross (*Phys. Rev.*, Nov. 1923, Proc Nat Acad Sci, July 1924), which had given the first definite proof of the existence of the Compton effect in elements other than carbon These new spectra showed the Compton-theory lines as strong as in the earlier spectra Apparently, therefore, these experiments confirm the calculations described at the Toronto meeting showing that those spectra were quite free from any contamination by box effects, and were due only to the elements to which Ross ascribed them.

Arsenic in Oysters.

YOUR contributor J. S G in reviewing (NATURE, December 20, p 913) the report of the Ministry of Agriculture and Fisheries on oyster mortality in 1920, and dealing with the finding of 3·7 parts of arsenic per million in oysters from certain beds, comments on the serious questions raised by such a fact. A definite pronouncement is needed as to what constitutes danger As is well known, the Royal Commission on Arsenical Poisoning, in its report in 1903, recommended that no substance used in the preparation of food should contain more than 1/100 grain per lb. This recommendation has been adopted as a standard for years, and many prosecutions have been successful for quantities but little in excess of this Surely the position is now more illogical than ever it was. Is the fishmonger to be prosecuted if his oysters have three parts per million (1/50 grain per lb.), and, if not, why should a grocer be charged if, say, a baking powder—probably not made by himself—contains this amount?

Results of investigation in Sweden show that fish may have an arsenic content up to four parts per million, and my own analyses of fish sold in the London market, recently communicated to the Society of Public Analysts, confirm this figure in respect of certain plaice. The administration of the Sale of Food and Drugs Acts in this respect requires revision.

Convective Equilibrium.

THERE is a rather important consideration connected with the production of cloud in rising air currents (which does not seem to have received attention) the effect of which is to check uprushes of moist air.

I have often noticed the cumulus clouds over a distant thunderstorm suddenly cease to rise and then disappear Whilst rising, their outlines are clear and sharp As soon as the rise ceases their outlines become indistinct Then a partially transparent veil appears where the cumulus cloud was, and this fades away entirely, leaving the atmosphere clear. Why do cumulus clouds fail to rise so high as one would expect them to?

Warm saturated air near the earth's surface (warmed by proximity to the ground) rises and steadily cools. After the dew point is reached important results follow Condensation takes place and the air is then prevented from falling in temperature so much as it would do if it were dry, and this would accelerate the velocity of the up current if it were not for the presence of the *newly formed cloud particles* The small drops forming the cloud are floating in the air and contributing their quota to its weight Condensation thus tends to check the ascent of the mass When the particles become large enough to descend quickly, as rain or hail, they draw the air down with them and the uprush ceases

The mechanical effect of falling rain, and the great density of a cloud due to the weight of the water particles in it, do not seem to have been generally considered R M DELLEY

Molecular Dimensions of Celluloid.

THE results of the experiments carried out by the Bureau of Standards, Washington (NATURE, December 13, p 861), are of very great interest, but would be still more valuable if the exact composition of the "celluloid" were known There is often confusion in referring to such words as "celluloid," "celloidin," "collodion" and the like Celluloid, the basis of photographic film, is certainly a manufactured mixture of variable composition, containing among other ingredients a considerable percentage of camphor, the main ingredient being, of course, a soluble cellulose trinitrate, though cellulose acetate is now being increasingly used on account of its non-inflammability. It is, therefore, scarcely correct to speak of the "molecular complex of celluloid" (unless "complex" is intended to cover a mixture of two or more compounds) "Celloidin" is the trade name of a carefully purified and soluble cellulose nitrate, probably approaching to a single chemical substance. Collodion is, of course, a solution of nitrocellulose in acetone, ether-alcohol, or some other organic solvent. HENRY GARNETT

ERRATUM.—In NATURE of October 4, p 490, a letter from Prof. Was Shoulejkin on "A New Method of Investigating Sea Waves" is subscribed "Technical High School, Moscow." The work described was carried out at the Physical Institution of the Science Institution of Moscow.

The Theory of Evolution since Darwin.[1]

By Prof. E. W. MACBRIDE, F.R.S.

NO event in the intellectual world has had such a profound influence on the mental outlook of mankind in general as the publication of the "Origin of Species" by Charles Darwin in 1859. A distorted version of the theory embodied in it figured largely in the propaganda that led to the Russian revolution. Nothing could be more interesting to the student of the history of thought than to analyse the ideas and assumptions involved in this theory and to trace their fate in the subsequent course of scientific criticism.

The outlines of Darwin's theory are familiar to all, and the technical terms which he introduced—"natural selection," "the struggle for existence," "the survival of the fittest"—have passed into everyday language. It is to be noted that he termed his theory "Descent with modification," and that the name "evolution" was first applied to it by Herbert Spencer. This is significant, because in Herbert Spencer's mouth, evolution denoted a general theory of everything that was going on in the universe, of which the development of animals and plants formed only a small part. We must emphasise, therefore, the fact that Darwin takes life and the fundamental properties of living things for granted; he does not strive, like Spencer, to explain them in terms of matter and motion.

Founding on what he could observe of the nature of life as he saw it, Darwin strove to argue back to what was the condition of the living world in past times and what are the influences at work in modifying it at the present time. He assumed that animals and plants are continually giving rise to small variations in all directions and that these variations are inheritable. This is the positive idea which is embedded in what is generally called the theory of "natural selection." For "natural selection," the death of the many and the survival of the few, is only the pruning knife and can of itself originate nothing new. These random variations Darwin attributed not to chance but to the environment, which, as Darwin imagined, produced an instability in the hereditary qualities of organisms which are exposed to new conditions. But besides this effect, Darwin asserted that the results of increase in size of organ by use and its diminution in size by disuse were inheritable. He was driven to this assumption by the endeavour to account for the disappearance of unused organs in such cases as that of cave-animals which had lost their eyes. He could not conceive how small decreases in size in organs which were no longer used could give their possessors the victory in the struggle for existence. Darwin imagined, further, that the struggle for a bare existence was in many species accompanied by a struggle to find a mate, a struggle which was undertaken by the male; and he attributed the varied peculiarities of colour, shape, ornaments, and voice which distinguished males from females, to the preference of the female for the most attractive male. The results of this supplementary struggle were termed by Darwin "sexual selection." This part of the theory has not met with general acceptance, and we can therefore leave it out of account.

The difficulties in his theory which Darwin felt most acutely were the beginnings of useful organs from small useless rudiments and the origin of the sterility which usually exists between allied species. The first difficulty has been largely removed by the progress of embryological research, for it has been shown that new organs do not originate from useless rudiments but by the modification of older and simpler organs, but the second difficulty has not been fully solved even to-day. Believing as he did that allied species were only more sharply differentiated local races of the same species, Darwin yet had to admit that local races were mutually fertile, and that allied species when crossed were sterile. He pointed out that sterility could arise between members of the same species as it has done in the case of the primrose, and he imagined that sterility was, so to speak, a by-product of increasing divergence of constitution.

Of course, as Darwin himself pointed out, many naturalists before him had interpreted the likenesses of allied species as evidence of blood relationship, and had even put forward speculations as to the course of evolution; but the weak point in all these theories had been that they did not point to causes now in existence by which evolution could have been brought about. The first effect of Darwin's theory was to convince scientific men, especially naturalists, that evolution really had occurred and that it was in fact still going on. The feature in the theory which secured their assent was "natural selection." It seemed to his contemporaries that Darwin had laid hold of a fact which, when once attention was directed towards it, no one could deny, namely, the death of the many and the survival of the few. It is true that Lamarck had previously relied on natural causes, such as the effects of use and disuse and the production of new habits as the agents in evolution, and I myself believe that he was in great measure right, but the changes of habits in animals which he postulates are phenomena which are slow in their effects and do not constantly occur, and they are not easily observable within the limits of a human life. Moreover, the facts which now give support to Lamarck's views were not known when he wrote, nor even when Darwin wrote, and hence Lamarck failed to produce an effect on contemporary thought at all comparable to that which was effected by Darwin.

Huxley in England and Haeckel in Germany were the great champions of the evolutionary principle against theological opponents. Haeckel[2] made to the theory one great addition which is of far-reaching consequence: it had been dimly perceived by Darwin and is hinted at in the "Origin of Species," but it was first clearly enunciated by Haeckel. In his "General Morphology," first published in 1866, he stated that "Ontogenesis, or the development of the individual, is a short and quick repetition (recapitulation) of phylo-

[1] From a lecture delivered at King's College, University of London, on November 28 for the Board of Studies on the History, Principles, and Methods of Science.

[2] My friend Prof. Dendy has pointed out to me that Haeckel derived his "Law of Biogenetics" from Meckel, who wrote in 1827, but as Meckel was opposed by von Baer, the great comparative embryologist of the day, his views were ignored.

genesis, or the development of the tribe to which it belongs determined by the laws of inheritance and adaptation." This in shortened form, "Ontogeny is a recapitulation of Phylogeny," was called the "Fundamental Law of Biogenetics."

The validity of this law Haeckel sought to establish by numerous examples, and he has been accused, apparently with justice, with misrepresenting some of the facts in order to bring them into conformity with it. He is said to have made four separate drawings of the same embryo and to have labelled them with different names so as to show the identity of the early embryonic form in four different groups This was detected, and together with the wildness of much of Haeckel's speculation tended, especially in Germany, to produce a strong reaction against most of Haeckel's teaching. But in spite of Haeckel's unscrupulous action he was in many respects a far-reaching genius Though some naturalists have affected to disbelieve in the biogenetic law, in practice, in their morphological reasoning all assume its validity Even Haeckel's special theory, namely, the derivation of the higher animals from a single hypothetical hydra-like ancestor, which he called the "gastræa," has received more and more confirmation as embryological research has proceeded

Haeckel never thought that variations could be due to chance, on the contrary, he attributes them all to differences in nutrition Some which we call "directly adaptive," like the effects of use and disuse, which alter the flow of blood to an organ and so change its nutrition, show their effects in a single generation, whilst others which he calls "indirectly adaptive" only make themselves felt in the next or succeeding generations He says that the "superiority of Englishmen is due to their being fed on excellent beef; but the beef results from the cattle being grazed on rich clover pasture. Clover is fertilised by wild bees, but wild bees are decimated by field-mice, which are kept in check by cats Cats are usually kept by old maids, and therefore this peculiarity of unmarried females is the original cause of British pre-eminence."

Huxley, though he contributed immensely to the building up of a scientific zoology on the basis of Darwin's theory, added nothing to the theory itself, but one of his sayings may be quoted as showing his insight into the matter at stake. "We have got our theory of evolution; what we want now is a good theory of evolution." We shall find that practically all subsequent criticisms of what for brevity's sake we may term Darwinism turn on these two questions, namely: (1) What is the nature and cause of variation? (2) Why are species usually mutually sterile?

We have already directed attention to the fact that the development of animals and plants from simpler ancestors was included by Herbert Spencer in his theory of evolution, a theory intended to explain everything that was going on in the universe on the basis of the laws of mass and motion. But Spencer laboured under all the disadvantages which beset those who write treatises on subjects with which they have only a second-hand or superficial acquaintance It is true that in his "Principles of Biology" he sees clearly that the vital point at issue in Darwinism is the origin of variations, and he throws his whole weight on the side of the inheritability of the effects of use and disuse. But his arguments are not convincing, since they always involve a "petitio principii", he never seems to see that a thorough experimental examination of the subject is necessary, but considers that his point is proved by vague plausible suggestions He suggests that animals are made up of "physiological units," and that these units become modified in response to changed conditions and are then passed into the germ-cells and make their effect felt in the next generation. This conception resulted from his comparison of the regeneration of the limb with the self-completion of a broken crystal in its mother liquor, a conception which we now know to be utterly futile and misleading. No doubt Spencer did much to popularise the idea of evolution with the general public, but it is impossible to point to one addition of any scientific importance which he made to the theory of evolution

It is true that Darwin in a later and far too imperfectly known book, "The Variation of Animals and Plants under Domestication," put forward a suggestion somewhat similar to that of the "physiological units" to explain the origin of variation This is the theory of "pangenesis" According to this hypothesis, every part of the body of animal or plant is continually throwing off "gemmules" which are endowed with the power of multiplication and with the capacity, in suitable circumstances, of growing into the likeness of the part from which they came These gemmules are carried from part to part by the circulation, and they accumulate in the germ-cells They become altered in character in accordance with the alteration of the part from which they come, and when sufficient of the altered gemmules have accumulated in the germ-cells, the alteration becomes hereditary. Darwin's gemmules, however, are living units endowed with the characteristic vital properties of growth and reproduction, whereas Spencer's physiological units are merely large organic molecules.

The next important event in the history of the theory of evolution is the advent of Weismann, who in 1885 published his "Essays on Heredity," which were later consolidated into a book termed "The Germ-Plasm" Until his time it had been tacitly assumed that the effects of use and disuse could be inherited, and the only reason for refusing to assign to them the exclusive importance attributed to them by Lamarck was the difficulty which many naturalists felt in explaining some evolutionary changes by the accumulation of the results of efforts on the part of the animals or plants which exhibited them. But Weismann challenged the validity of the whole of the Lamarckian doctrine, and this he did on two grounds first, that the evidence in favour of acquired characters was not sound, and secondly, that on account of the structure of what he calls the "germ-plasm," acquired qualities could not be transmitted. He therefore sought to explain the origin of variations by what I can only term the accidents besetting the ripening of the egg. Since all the father's potencies in heredity are contained in the sperm-head, which is a condensed mass of chromosomes equal in number to those in the ripe and unfertilised egg, the real bearers of hereditary powers must be the chromosomes.

If now we suppose that a single chromosome, which Weismann terms an "idant," nay, even a portion of a chromosome which he calls an "id," is theoretically capable of carrying out the entire development of the species, but that different "ids" would give rise to slightly different types of development and that the actual development of the egg is a compromise between the potencies of the various "ids," we arrive at the Weismannian explanation of variations. If it is mere chance which group of "ids" are thrown out of the nucleus when the number of chromosomes is halved at ripening, then obviously all sorts of different groups may be left in the make-up of the various eggs and various sperm-cells, and these different groups will give rise to different inheritable variations of which natural selection will preserve those best adapted to the circumstances of the animal

But why should the various "ids" differ from one another? To this question an extraordinary answer was given by Weismann When a cell divides, the nucleus divides first and each chromosome gives rise to daughter chromosomes by longitudinal splitting, which then by nourishing themselves at the expense of the protoplasm grow as big as their parent. During this growth, variations in nutrition of the daughters are the causes of variations in their structure which are handed on to their posterity at the next division! So that the very principle which Weismann rejects at the beginning of his hypothesis, he reintroduces in dealing with the chromosomes, namely, external circumstances giving rise to inheritable variation Let us now glance for a moment at the way in which the theory is worked out in detail. The fertilised egg begins its development with a selected group of "ids" derived in equal proportions from the father and the mother; each of these "ids" contains within it the entire potency to bring about the development of the adult form. When the egg-cell divides, the division, though apparently an equal one, is in reality unequal—one daughter retains the "ids" undisturbed, but in another the "ids" have already undergone decomposition and are now represented only by "determinants," each of which has only the potency of causing the development of that part of the body to which this daughter-cell will give rise. As development continues, the determinants suffer further decomposition until at length they are resolved into "biophores," which have only the capacity of conferring on the cell in which they lie the power to become a muscle-cell, a nerve-cell, a gland-cell, etc The descendants of the other daughter-cell of the original two, however, receive unbroken "ids" and eventually give rise to the germ-cells of the next generation Their lineage is called the "germ-track"

On the Weismannian hypothesis, then, the germ-cells are separated from the body at the very beginning of development and are not afterwards influenced by what happens to the body during its growth, and Weismann, with true Teutonic thoroughness, having formed this conception of the structure of animals, declares it be *a priori* impossible that acquired characters, *i.e.* new habits, could affect the germ-cells, since, as he states, he can form no conception of how the change in structure resulting from a changed habit can be represented in the nucleus of the germ-cell. The experiments alleged to prove the inheritance of acquired qualities which were available to Weismann were supposed examples of the hereditary transmission of mutilations; these he sought to explain away, and he cut off the tails of mice and bred from these maimed animals, and showed that the offspring did possess well-developed tails.

Weismann's doctrines obtained wide acceptance, and were regarded as finally disproving the environmental origin of variations, and the position remained practically unchanged until the beginning of the twentieth century.

We may now pause for a moment to take up the question of the sterility between species. In 1897, Romanes, a Cambridge man who had migrated to Oxford, published a book entitled "Darwin, and after Darwin." In this book he considers the question of how two divergent species could have arisen from one, and he points out that it is inconceivable that this could have happened by the natural selection of accidental variations, unless two portions of the original species had become isolated from one another so that cross-breeding was prevented. Romanes puts forward the idea that owing to accident (*i.e.* unknown causes) physiological variations occurred, so that two portions of the same stock became mutually sterile. He thinks that geographical isolation is insufficient to account for the appearance of sterility, because species occupying adjacent territories are often mutually sterile, and he cannot conceive how what seem to him slight differences in climate can effect so great a change as sterility, but as to the causes of the appearances of this "physiological isolation" he gives no hint whatever. No further light was thrown on this subject until the last year or two, when Goldschmidt took up the question of the mutual fertility of local races of the same species when crossed. He showed in the case of the gipsy moth that when two races from widely separated localities are crossed, sterile intersexes are often produced which render the continued propagation of the mixed race difficult. His results therefore support Darwin's hypotheses of sterility as a by-product of increasing divergence of constitution.

The twentieth century began with two events of decisive importance for the theory of evolution; namely, the rediscovery of Mendel's researches by Correns in 1900 and the publication by Johannsen in 1903 of a paper entitled "The Bearing of Pure Lines on the Theory of Inheritance." Mendel's researches, which were carried out at the same time as Darwin's work and published soon after the publication of the "Origin of Species," appeared in local journals of too limited circulation, and attracted no notice from the general scientific world. They had in Mendel's mind no relevancy to the formation of species whatsoever, but were concerned only in discovering the laws governing the distribution of paternal and maternal characters amongst hybrid offspring. Mendel in his experiments always chose varieties sharply separated from one another by definite clearly-cut characters. The rediscovery of Mendel's work gave a great impetus to the carrying out of experiments in crossing all kinds of variants from the normal with the type. In these experiments Bateson in England and Morgan in the United States took leading parts, and it was soon dis-

covered that those sudden deviations from the normal which turn up without assignable cause in most breeds of domestic animals and varieties of cultivated plants obey the Mendelian rules when crossed with the types Johannsen's results proved the non-inheritability in the case of beans of those small random deviations from the normal in all directions on which Darwin had laid such stress, and these results were independently confirmed by Jennings, who worked on Protozoa, and by Agar, who studied small Crustacea (1912).

In consequence of these discoveries, biological opinion veered round in favour of regarding the conspicuous aberrations commonly known as sports as the raw material on which natural selection had worked Darwin, it is true, had considered the question of whether sports might not be the starting-point of new species, and had decided that they could not be so on account of the rarity of their occurrence. He thought that the chance of such a sport mating with its like, even if highly successful in the struggle for existence, was infinitesimal, and that if it did not mate with its like its characters would be "swamped by intercrossing" But if the deviation were in a direction favoured by natural selection, it might be assumed that it would make itself felt in lesser degree even when its orginal possessor crossed with the type, and the first generation descendants might still survive on account of its lessened manifestation Many have claimed that this argument is strongly reinforced by the discovery of the laws of Mendelism. For if the deviation behaved as a dominant when crossed with the type, all the first generation of the descendants of such a cross would show it in as strong a manner as its orginal possessor; and even if it were recessive it would appear in undiminished strength amongst one-fourth of the second filial generation. The real objection to regarding sports as the initiators of new species lies deeper An animal does not survive on account of one organ. In its growth from the egg to the adult, it runs the gauntlet of many dangers, and a strong development of some one organ might determine its survival at one period of its existence, but if the deviation occurs very rarely the chances against that particular animal reaching the critical stage at all are enormous.

De Vries, the director of the botanical gardens at Amsterdam, carried out between the years 1886 and 1899 a series of cultures of the garden plant *Œnothera Lamarckiana*, commonly known as the evening primrose He showed that every year a number of sports turned up, usually about half a dozen in 10,000 specimens, sometimes as many as three in a hundred, and that this sports usually, though not always, bred true when crossed with their like De Vries called these sports "mutations," and imagined that he had surprised a species in a "fit of mutation," and that new species were not produced by a slow process of differentiation but by sudden jumps, so that they began their existence complete in all their details, as Minerva sprang from the head of Jove. The De Vriesian doctrine joined with Mendelism, and became the dominant doctrine of evolution and heredity for most of the first quarter of the twentieth century, and probably counts amongst its adherents a larger number of biologists than any other doctrine at the present time. It was first seriously put forward by Bateson in 1894 in a book entitled "Materials for the Study of Variation," in which he figured and recorded a large number of examples of monstrous deviations from the normal, and laid down two doctrines, one of which is undeniably true, whilst the second is really the De Vriesian theory. The first was "variation is evolution", the second, the "discontinuity of species is due to the discontinuity of variation"

The De Vriesian view has reached its climax in a book termed "Age and Area" by Dr Willis, a distinguished botanist. This book was published two years ago, in it Dr Willis supports the idea that species originate in sudden inexplicable jumps which occur only rarely. This idea is difficult to distinguish from the pre-Darwinian doctrine of special creation No wonder that Haeckel, who lived long enough to encounter this view in its early presentation by Bateson, said "If views like this are to be accepted, it would be better to return to Moses at once"

(To be continued.)

Biographical Byways.

By Sir ARTHUR SCHUSTER, F.R.S.

INTRODUCTION.

THERE are things seldom referred to in obituary notices and sometimes omitted even in more ambitious biographies. They tell the tale of peculiarities or weaknesses, which the writer fears may detract from the merits of the man he has set out to praise. The biographer believes, with some show of justice, that his main object is to give a record of work accomplished and not a psychological analysis of character. But eccentricities, or even decided failings, form part of a man's personality. The extent to which his teaching carries conviction and affects the scientific outlook of his time, depend as much on his personal attributes as on the merits of his researches. We destroy the balance of a just valuation, if we ignore those shades of character or temperament which act as handicaps to the full fruition of his work.

It has been my good fortune to be acquainted personally with many of the men who laid the foundations of the science of the nineteenth century, and I have retained a vivid memory of such intercourse as I had with them In writing down some of my recollections I have tried to outline personalities in a sympathetic spirit. If human frailties are sometimes exposed, I hope that the limits of allowable candour have never been transgressed, and that, apart from the personal factor, the incidents related may be found to contain some substantial contributions to the history of science during the middle period of last century

1. URBAIN JEAN JOSEPH LEVERRIER (1811–1877).

Towards the end of December 1874, or nearly in the year 1875, I received an invitation from the Royal Society to take part in an expedition which was being

organised to observe the total solar eclipse of April 1875 in Siam. Norman Lockyer was expected to act as leader of the expedition, which was to start in February; the time for preparation was therefore short. Ultimately Lockyer, who was then acting as secretary to the Royal Commission on Science Teaching presided over by the Duke of Devonshire, did not obtain the leave of absence he had expected, and I was put in charge. I had never had any experience in mounting or dismounting astronomical instruments, or indeed in using them, and one of the appliances on which we depended—a large siderostat—was under construction and not expected to be ready before the eve of our departure. It was essential that I should get some knowledge of the instrument, and more especially of the process of silvering the mirror, which was to be a foot in diameter. A similar siderostat was in use at the Paris Observatory, where M. Adolphe Martin had found a simple and convenient method of silvering large surfaces of glass. I was therefore sent to Paris, the consent of Leverrier, the famous director of the Observatory, having been obtained.

I first called on Cornu to ask advice on some optical questions that had arisen and, needless to say, I met with a most friendly reception both from him and other scientific men, notably Jamin. When Cornu heard that I was to call on Leverrier, he shook his head and said: "Je ne sais pas si M. Leverrier est l'homme le plus détestable à Paris, mais je sais que c'est l'homme le plus détesté." This was not encouraging, and it was in fear and trembling that I entered the Observatory.

I was received by one of the assistant observers, C. Wolf, who remarked with a look full of sympathy. "You will find M. Leverrier in a very bad temper: he has just returned from a funeral." I was then barely twenty-three years old, and naturally looked upon Leverrier (who was then sixty-four) as one of the formidable veterans of science. I was ushered into the "Presence," received with a searching look and the abrupt question: "Qui êtes-vous et que voulez-vous ici?" I mildly answered that I understood Mr. Lockyer had written to explain the purpose of my visit. "So he has," said Leverrier, "but I want to hear it from you." After I had replied to the best of my ability, I was dismissed with the remark: "I have already given instructions that every assistance should be given you."

I spent an interesting and instructive week practising Martin's silvering process, which has the great advantage that the surface comes out polished, except for a thin veil which is easily removed without appreciable friction. When it was time to return home, I suggested to M. Wolf that it might be sufficient for me to write a letter of thanks to Leverrier without troubling him with a personal call. But Wolf would not hear of this, and I was shown again into the "lion's den." Leverrier was sitting at his desk, and by his side stood a trembling young assistant to whom he continued to speak, taking no notice of me. I listened to a conversation of which I remember the main points without pretending to literal accuracy.

LEVERRIER. And so you tell me, that after trying for a whole week you have not yet found the mistake in your calculations?

ASSISTANT. No.

LEVERRIER. You have, of course, applied the correction for . . . (I did not catch the details).

ASSISTANT. Yes.

LEVERRIER. Did you apply it with a plus or a minus sign?

ASSISTANT. Plus.

LEVERRIER. It ought to be minus. That is your mistake. Go and correct your calculations.

After the assistant had left the room, Leverrier chuckled. "I knew all along," he said to me, "what his mistake was, but I wanted to see whether he could find it out by himself"; and to my great surprise he continued, "come and have a walk round the garden." All traces of peevishness and severity had disappeared, and for half an hour or more he became a most interesting and encouraging talker. A new reflecting telescope was just being erected in the grounds of the Observatory, and he explained the uses to which it might be put, inviting me, whenever I felt inclined, to come and work with it.

He then began to speak on a subject on which he evidently felt very strongly. Great preparations had been made in the previous year, and much money spent, on fitting out expeditions to observe the transit of Venus, which had just taken place on December 8, 1874. The French Government had followed the example of other countries, but against Leverrier's advice. It was, of course, well known to astronomers that he preferred other methods of determining the solar parallax, but the Government would not listen to his advice. "Que voulez-vous?"—France had recently been defeated in war, and if she did not share in international work, the Government was afraid that its action might be misinterpreted and believed to be due to sulkiness or want of funds. But Leverrier strongly expressed his opinion that the money was all wasted, and that neither this nor the subsequent transit of 1882 would add anything of value to our knowledge. In this he proved to be perfectly right.

2 JOHN PRESCOTT JOULE (1818–1889).

I once asked Joule what he felt like when he heard that one of his papers was rejected by the Royal Society. "I was not surprised," he answered, "I could imagine these gentlemen in London sitting round a table and saying to each other: 'What good can come out of a town where they dine in the middle of the day.'"

There are some interesting and somewhat puzzling circumstances connected with the fate of that paper, which was communicated to the Royal Society by one of its secretaries, Peter Mark Roget, on October 16, 1840. Under the title "On the Production of Heat by Voltaic Electricity," it contained the account of an experimental investigation which had led Joule to formulate his all-important law, that the heat generated in a conductor by an electric current is proportional to the product of the resistance and the square of the current. The paper was read on December 17, and in due course a short abstract appeared in the Proceedings which gave the final result arrived at, and hence secured Joule's priority. It is, therefore, not quite correct to say that the paper was rejected. The difficulty arose in connexion with its publication *in extenso*. The paper was short—it would not have taken up more than four or five pages in the Proceedings—and it was perhaps

considered that such far-reaching results could not be proved by the comparatively few experiments conducted by Joule. Criticisms were also made on the ground that previous investigations on the same subject were not mentioned On March 11, 1841, the communication was committed to the Archives.

A paper carrying the title "On the Heat evolved by Metallic Conductors of Electricity and in the Cells of a Battery during Electrolysis" shortly afterwards appeared in the *Philosophical Magazine*. It bears the date March 25, 1841, and its introductory paragraph concludes with the sentence:

> "I hope therefore that the results of my careful investigation on the heat produced by voltaic action are of sufficient interest to justify me in laying them before the Royal Society."

This remark has naturally led to the belief (definitely expressed by Osborne Reynolds in his extensive memoir on Joule published by the Manchester Literary and Philosophical Society) that the paper, as printed in the *Philosophical Magazine*, is the one declined by the Royal Society. This, however, is not the case. The difference in the title is significant. The Royal Society paper deals with solid conductors, covering only the ground which in the *Philosophical Magazine* appears as "Chapter 1," and is there followed by a second chapter, twice as long, dealing with electrolysis and adding considerably to the range and importance of the results Even in the first part the two papers are not identical, only a few short paragraphs being unaltered though it must be admitted that the alterations are not material. It is not at all certain whether the complete paper as it appeared in the *Philosophical Magazine* would have been declined by the Royal Society, but it is perplexing that the reference to the Royal Society has been left standing in the altered and extended paper.

We cannot suppose that Joule deliberately wished to convey a wrong impression, and only one explanation seems to me to offer itself. It may be surmised that some correspondence took place in the three months between the date at which the paper was read and that at which it was committed to the Archives On being informed of the objections raised, Joule may have prepared a more complete account to be substituted for the paper originally submitted; but the Royal Society having finally declined to print the original paper *in extenso*, he was quite likely to forward the amplified version to the *Philosophical Magazine*, the reference to the Society in the opening paragraph being left standing by an oversight.

It is not my desire to acquit the Royal Society of all blame, but mitigating circumstances might be urged. Joule's experiments no doubt appear conclusive to us, but the very simplicity of his experimental arrangements, and the comparatively few numerical results given, may have raised doubts which were perhaps excusable. The heat generated was determined by the rise of temperature of a measured quantity of water in which a coil of uncovered wire was inserted, and no cooling correction was applied. Though Joule gave good reasons why these simplifications did not affect the result, such cavalier treatment of the minor sources of error may have shocked the academically-trained mind as showing want of respect for the dignity of the problem It is seldom that referees can rise to the standard of Stokes, who, in reporting on a communication by an eminent man of science possessing great intellectual powers not always assisted by clearness of expression, gave his judgment as follows:—"The first part of the paper I can understand but do not agree with, the second part I cannot understand, but as the results arrived at may be important I recommend that the paper be published in the Philosophical Transactions"

Joule's later work is so intimately connected with the determination of the mechanical equivalent of heat, that the importance of his investigations in other domains is apt to be overlooked. The two volumes of his published researches show that he was by no means a specialist, but only those who knew him personally are aware of the extent of his knowledge and broadness of interests ranging over nearly all branches of physics. He was a pupil of Dalton, who had refused to instruct him in chemistry before he had learned the elements of mathematics. It was perhaps in recollection of his first teacher of science that Joule once remarked to Balfour Stewart "If I were a young man I would concentrate my attention on atomic weights" When I first became acquainted with Joule, he was a little more than sixty years of age and in full vigour The meetings of the Manchester Literary and Philosophical Society in those days will always remain in the memory of those who were fortunate enough to attend them It was the custom then, and I believe is still, to devote the first half-hour to a discussion on any subject brought forward by some member, spontaneously or at the invitation of the president A regular attendant, Joule was at his best on these occasions He also made his presence felt at the council meetings as a confirmed conservative opposed to all changes His health began to fail about 1882, but in November 1885 he dined at my house to meet the late Lord Rayleigh, who had come to Manchester on purpose to make his acquaintance. "I believe I have done a few little things but nothing to make a fuss about," he said, shortly before his mental powers began to fail

After Joule's death, I was asked by his family to examine his apparatus and instruments—mostly constructed by his own hands—and I was fortunate to rescue his historical thermometers, which were lying covered with dust in an old stable attached to his residence I was thus enabled to determine the difference between the scale value of the thermometer used by Joule and that of the standard of the Bureau international des Poids et Mesures. It appeared in the investigation that the glass of Joule's thermometers is more suitable to its purpose than the glass afterwards employed in England. The depression of the zero after being raised to a definite temperature is much smaller and more nearly approaches that of the hard glass used by French makers. These thermometers were presented by Joule's son to the Manchester Literary and Philosophical Society: most of the remainder of Joule's apparatus is preserved in the Physical Laboratories of the University of Manchester

Current Topics and Events.

WE are glad to see that noteworthy recognition is accorded to science in the New Year honours list which was issued last week The appointment of Sir James G. Frazer and of Sir Ernest Rutherford to the Order of Merit, an order which was "designed as a special distinction for eminent men and women" and is limited to twenty-four members, will give particular pleasure to scientific workers everywhere Included among the honours are also the following — *Knights*, Prof John Adams, Professor of Education, University of London, 1902-1922, Prof. R H. Biffen, Professor of Agricultural Botany, Cambridge University, Mr G R Clarke, Director-General, Posts and Telegraphs, India, Dr Hari Sing Gour, Vice-Chancellor, Delhi University, Mr W. B Hardy, Secretary of the Royal Society, Prof F Gowland Hopkins, Professor of Bio-Chemistry, University of Cambridge, Principal J C Irvine, Principal and Vice-Chancellor of the University of St Andrews, Mr F Truby King, Director of the Child Welfare Division of the Department of Health, Dominion of New Zealand, Dr. T. M Legge, Senior Medical Inspector of Factories, Mr B Longbottom, Chairman, British Electrical and Allied Manufacturers' Association, Maj.-Gen R C Macwatt, Director-General, Indian Medical Service, Mr F W Petter, President, British Engineers' Association, Dr H J Waring, Senior Surgeon, St Bartholomew's Hospital, Vice-President, Royal College of Surgeons, Vice-Chancellor of the University of London, 1922–1924 *C.I.E*: Mr H G Billson, Chief Conservator of Forests, and Member of the Legislative Council, United Provinces, India *D B E* (*Civil Division*) Miss L B Aldrich-Blake, Dean of the London School of Medicine for Women

AMONG the mechanical inventions which revolutionised the cotton industry was the cotton gin of Eli Whitney, whose death took place on January 8, 1825—a hundred years ago The flying shuttle of Kay, the spinning jenny, the water frame and the mule of Hargreaves, Arkwright and Crompton, together with the power loom of Cartwright, increased enormously the rate of spinning and weaving, but the cleaning of the cotton fibre from the seed was still largely done by hand. Whitney's great invention was made in 1792, and in about ten years the export of cotton from the United States rose from less than 200,000 pounds to more than 40,000,000 pounds per annum. The essential parts of Whitney's machine consisted of a grid on to which the seeds were fed, a revolving wooden cylinder studded with wire teeth which tore the fibre from the seed, and a revolving brush which in turn removed the fibre from the wires One such machine would do the work of 50 men engaged in hand-picking. Whitney was born in 1765—the same year as Fulton—and was the son of a farmer of Westboro, Massachusetts. He worked as an artisan, made money by teaching, and in 1792 graduated from Yale When about to take up a post as tutor, a chance conversation led to his tackling the problem of cotton cleaning. His gin soon came into use and he had to establish his claims by much litigation. Later, he founded a factory at New Haven for the manufacture of fire-arms and was the pioneer among Americans in the modern methods of making large numbers of interchangeable parts He died at New Haven, leaving a part of his fortune to Yale for the purchase of books on physical and mechanical science

THE year 1924 was a year of notable centenaries, but one of scientific interest seems to have been overlooked, namely, that of the establishment of the first physiological laboratory in Europe The man who opened this laboratory in the year 1824 was Johannes Evangelista Purkinje, at that time professor of physiology and pathology at the University of Breslau It has been suggested that it was through Goethe's influence that Purkinje was appointed to this chair, for the author of "Faust" reckoned him as one of his friends, their common interest being in subjective visual phenomena. The reception given by the Prussians to the Bohemian Purkinje was far from cordial, but by his amiability and scientific gifts he lived down all opposition. The laboratory of 1824 was not housed in any building belonging to the University but in the professor's private dwelling. Doubtless the establishment of this first of European physiological laboratories attracted no attention from the contemporary journalists, but when we reflect on the immense benefits which have accrued to medical science from the findings in the laboratories of practical physiology—insulin being one of the latest—all men of science will like to remember that it is just a few days more than one hundred years ago that the academic pursuit of that subject was inaugurated So far as we can gather, the instruction in Purkinje's laboratory was chiefly in histology, a subject which the anatomists willingly allowed the physiologists to teach for the next century It is only now that that portion of the physiologists' burden is being cast, where it belongs, upon the shoulders of the morphologists.

A WRITER who signs himself "Poetarum Minimus" enters a plea in the *Scientific Worker* for December for the exercise of poetic expression in scientific fields, and as an example he submits a contribution having for its theme the evolution of stars from "tenuous mists" up to maturity and down to decay. Thus,

A hundred million million years they scatter largesse of their rays
They spend their substance royally throughout the measure of their days.

The verses from which these lines are taken have commendable dignity and sound, and they are reminiscent of the style of Erasmus Darwin, who essayed similarly to express views of the stellar universe current in his time in the sonnet, "Roll on ye stars, exalt in youthful prime." Tennyson surpassed all other poets in the application of scientific truth to poetic purpose, and his astronomical allusions are particularly fine, as, for example, in "This world was once a fluid haze of light," and "Regions of lucid matter, taking form: Brushes of fire, hazy gleams."

Several years ago the geological course of events, from "Nebula to Man," was described in verse in a sumptuous quarto volume by the late Mr. Henry Knipe, and Mr. Alfred Noyes has given us his beautiful epic, "The Torch-bearers," which is on a much higher plane. Poetry, however, is something more than accurate description in verse form It should, of course, have a certain beauty of sound when spoken, but its main function is the creation of stimulating thoughts which appeal to the human heart rather than to the intellect. While, therefore, we may believe that the wonders of modern science furnish rich material upon which poetic imagination may be worthily exercised, we cannot forget that emotion is independent of knowledge, and that, as Coleridge said, science seeks to know and communicate truth—acceptable or not—but the chief purpose of poetry is to give pleasure The difference is aptly expressed by Sir William Watson in one of his epigrams, thus.

Science and Art, compeers in glory,
Boast each a haunt divine
"My place is in God's laboratory,"
"And in His garden mine"

A NEW Research Institute for the improvement of crops, at which special attention will be paid to cotton and to the fundamental problems underlying the production of this crop in India, was formally inaugurated at Indore in Central India on November 24 last. The foundation of this new Institute has been rendered possible by the provision of a valuable site of 300 acres by the Indore Durbar, by a grant of two lakhs of rupees (about 15,000*l*.) for capital expenditure by the Indian Central Cotton Committee, and by an annual contribution of 120,800 rupees a year (a little more than 9000*l*.) for current expenses in addition to the income derived from the land at the disposal of the Institute This annual grant has been provided jointly by the Indian Central Cotton Committee and by seven of the Central India States (Indore, Dhar, Jaora, Datia, Rutlam, Dewas Senior Branch, Narsingharh and Sitamau). The control of the Institute has been vested in a governing body of six members with the agent to the Governor-General in Central India as president. Three members of the board of governors are nominated by the Indian Central Cotton Committee, one by Indore Durbar, and two by the rest of the contributing States. The Director of the Institute will act as agricultural adviser to the States, and will in this way come in direct touch with the Malwa plateau, one of the most important cotton tracts in India.

THE experimental area which will be at the disposal of the new Research Institute, has been leased by the Indore Durbar to the Institute for 99 years at a nominal rent of 2*o*l. a year; it embraces all the types of black cotton soil met with in India, and is very favourably situated for research work on crops. It is close to the city of Indore, now rapidly growing in importance as a commercial, manufacturing, and educational centre, and to the cotton mills. The maintenance of an up-to-date library on crop-production and the training of post-graduate students, selected by the Indian Central Cotton Committee, will be features of the Institute. Mr Albert Howard (formerly Imperial Economic Botanist at the Agricultural Research Institute, Pusa) has been appointed Director of the Institute and agricultural adviser to States in Central India, and Mrs Howard (formerly second Imperial Economic Botanist at Pusa) will be employed as physiological botanist at Indore

ON Tuesday, January 6, Sir Oliver Lodge gave the first of his series of seven fortnightly talks on "The Ether of Space and its Functions," under the auspices of the British Broadcasting Company at 2LO, which was relaid to many stations in the British Isles, and also to the longer wave high-power station 5XX at Chelmsford The first talk was entitled "First Notions about the Ether How Matter is held together, and how we see it" After describing the functions and uses of the ether, Sir Oliver went on to explain that matter was discontinuous, consisting of isolated particles not in contact, and was only held together by cohesive forces existing in the ether He supposed that if we could magnify a piece of matter to an impossible extent, it would have an appearance something like the midnight sky, where the separated pieces of matter are similarly held together or united into systems by the force of gravitation—which also is a function of the ether So that the ether is a great unifying entity, without which there would be no cosmos, but chaos. Sir Oliver concluded his first talk thus "You cannot imagine empty space being thrown into vibration; there must be something in space which vibrates, and that 'something' extends to the furthest visible object, and constitutes a unifying and connecting mechanism, through which all our information is obtained . . We have as yet very little acquaintance with the universe, sometimes we seem to know a great deal, at other times we realise that we hardly know anything The mystery of it all escapes us, and the possibilities of it are beyond our conception many of them we could not apprehend if they were explained to us, we have not the terms or ideas to understand them Meanwhile we grope along as best we can, and do our daily work with a keen expectation of the future, and he is wisest who denies least of the mystery which surrounds us and the possibilities ahead. To assert, requires knowledge, to deny, requires much more knowledge Let us be satisfied with positive knowledge so far as it has been vouchsafed to us, and leave negations to the self-sufficing and the omniscient. We can deny the self-contradictory and the absurd, but in the unknown and the mysterious, denials have no legitimate place: our business is carefully and cautiously to ascertain what is. We are surrounded by infinity, infinities of various kinds; and the wealth of existence is such as to justify a faith in our highest conceptions, a hope in the possibilities which lie before us, and a charity which enables us to do our daily work and to love our fellow men."

GREENWICH weather observations, which give approximately the average conditions over England,

show that 1924 was generally wet and unseasonable The winter months were mostly mild, while the summer months were mostly cool, and all months were wet with the exception of February, March, and August The mean temperature for the year 1924 was 50° 6 F., which is 0° 5 F in excess of the normal The warmest month was July, with the mean temperature 63°, which is 0° 5 below the normal; the coldest month was February, with the mean temperature 37° 3, being 2° 5 below the normal December was 3° 5 warmer than the average, and there were only three nights, December 9-11, with frost in the season June, July, and August were the only months with a temperature of 80° or above, the highest reading being 89° on July 12 The lowest temperature during the year was 21° on February 15 Rain fell on 168 days, yielding a total of 31 inches, which is 7 5 inches more than the average for thirty-five years The wettest month was July with 4 20 inches, which is 2 inches more than the normal The driest month was February with 0 65 inch, and this was followed closely by March with 0 69 inch, the deficiency for the two months combined being 2 inches 1924 is the wettest year since 1903, when the annual measurement was 35 54 inches In the dry year of 1921 the total rainfall at Greenwich was only 12 50 inches, in 1923, a normal year, the measured rain was 23 86 inches Sunshine was generally deficient, the only months with an excess of sunshine being January, March, July, and December Records of temperature and rainfall for London now extend over about the last 200 years, but careful examination of these fails to give any cycle or periodicity which can help in the prognostication of the weather for a coming year or season; 1925 has started with exceptionally wet and boisterous conditions

ONE of the recommendations made last year by the Departmental Committee on the Fertilisers and Feeding Stuffs Act, 1906 [Cmd 2125], was the appointment of a committee to consider the articles to which revised legislation should apply This advisory committee, which has power to co-opt, has now been constituted as follows Lord Clinton (chairman), Mr E. G Haygarth Brown, Dr Charles Crowther, Mr J Garton, Mr C W. Higgs, Mr Arthur Holgate, Mr. Thomas Kyle, Mr. Alexander Main, Lieut.-Col. R L Norrington, Mr. J W Pearson, Mr R R Robbins, Sir E J Russell, Mr John Speir, Mr. George Stubbs, Dr J F Tocher, Prof T. B. Wood, and Mr H. J Johns, of the Ministry of Agriculture and Fisheries, 10 Whitehall Place, S W 1 (secretary) According to the terms of reference, the committee is to draw up schedules prescribing the fertilisers and feeding stuffs to which the proposed legislation on the lines of the Report of the Departmental Committee on the Fertilisers and Feeding Stuffs Act, 1906, should apply, and methods of defining and stating the constituents and the "worthless" and "deleterious" commodities are to be considered

AN interesting new departure in tourist travel is the motor tour across the western Sahara to Timbuctoo Citroën Cars, Limited, the organisers of the tour, have sent us an itinerary of the route. The cars leave Colomb-Bechar, the railway head of the Algerian railway, and pass by Igli and Beni-Abbes to Adrar, the centre of the Tuat region. Thence they pass by Taouriot and strike almost due south, reaching the Niger at Burem. From Burem the traveller can continue in cars to Gao or Niamey, with the alternative of going by motor boat to Kabara and car to Timbuctoo. From Colomb-Bechar to Timbuctoo by this route is 1700 miles, and the time occupied is eight days Timbuctoo is thus brought within twelve days of London, and there is a trans-Sahara service twice weekly. Modern hotels have been constructed at Colomb-Bechar, Beni-Abbes, Adrar and Timbuctoo, while at other stopping-places the company maintains camps It is of interest to note that this motor service to Timbuctoo has been instituted within a year of the centenary of the first European traveller entering what was then the mysterious city

MR MURRAY MACGREGOR, district geologist, has been appointed assistant director of the Geological Survey in Scotland in succession to Dr Walcot Gibson

IN connexion with the Liverpool Section of the Society of Chemical Industry, Sir Max Muspratt, Bart., will deliver a Hurter Memorial lecture in the chemistry lecture theatre of the University of Liverpool on Friday, January 16, at 8 o'clock, on "Chemistry and Civilisation"

PROF G T MORGAN, professor of chemistry in the University of Birmingham, has been appointed Superintendent of the new Chemical Research Laboratory of the Department of Scientific and Industrial Research at Teddington Prof Morgan was awarded the Research Medal of the Worshipful Company of Dyers in 1922 for his work on the co-ordination theory of valency in relation to adjective dyeing, and he is the author of numerous original papers in various branches of chemistry published by the Chemical Society, Society of Chemical Industry, and other societies

APPLICATIONS are invited for some junior assistantships at the National Physical Laboratory, Teddington Candidates must possess a good honours degree or equivalent qualification in physics, engineering or electrical engineering, and preferably with some experience in research Application forms can be obtained from the director of the laboratory. They must be returned to him by, at latest, January 17.

ACCORDING to the New York correspondent of the *Times*, the trustees of the Metropolitan Museum of Art have announced the gift to that institution by Mr John D. Rockefeller, junior, of 16,000 shares in the Standard Oil Company of California. These shares are worth approximately 200,000*l*. The gift is made unconditionally, but the donor suggests in his letter to the trustees that it should be added to the endowment fund.

ON Tuesday next, January 13, at a quarter past five, Prof. A. Fowler will begin a course of two lectures at the Royal Institution on the analysis of spectra,

and on Thursday at the same hour Mr Julian Huxley will deliver the first of two lectures on the courtship of animals and its biological bearings The Friday evening discourse on January 16 at 9 o clock will be delivered by Sir William Bragg on the investigation of the properties of thin films by means of X rays and on January 23 by Dr A W Crossley on science and the cotton industry

THE third meeting of the Society for Experimental Biology was held at Cambridge on December 19 and 20 the different sessions being held in the Schools of Zoology and Physiology Members were entertained at lunch in Caius College by Prof J Stanley Gardiner and a dinner was held in Christ s College The programme included a paper by Prof J Barcroft on Hæmoglobin as an Example of the Evolution of a Chemical Mechanism a discussion by Dr H H Dale on The Nature of the Active Substances in the Posterior Lobe of the Pituitary Gland and a symposium on The Rôle of Electrolytes in the Organism in which Messrs A J Clark J Gray and J B S Haldane took part A number of other papers of interest were presented Fifteen new members were elected

SIR NAPIER SHAW has published privately a Kalendar for 1925 arranged in weeks showing the seasons and the international days for observation of the upper air This is followed by a detailed list of the daily observations of solar and terrestrial radiation made in England during 1924 For each day of the year there is shown the sun s declination the measurement of solar intensity at Kew Observatory between 11h 30m and 12h 30m the observations at South Kensington and Rothamsted of the maximum intensity of radiation from sun and sky and of the total radiation during the day upon a horizontal surface and measurements of incoming and outgoing long wave radiation made at Benson on cloudless evenings These observations are given in weeks with the unusual but convenient arrangement of giving on each page two weeks which are separated by an interval of six months The addition and subtraction of observations separated by six months gives the even and odd harmonics of the radiation curve separately The Kalendar thus contains in readily accessible form much information of great value to meteorologists and others interested in solar and terrestrial radiation

Two books of ethnological interest are announced for publication by Messrs Seeley Service and Co Ltd namely The Menace of Colour by Prof J W Gregory dealing with many of the interracial problems of the day and pointing out the dangers of the rising tide of colour and how they may be met or avoided and Vanishing Tribes of Kenya by Major Orde Browne Senior Commissioner of Tanganyika a record of the habits and customs of the tribes inhabiting the slopes of Mount Kenya

Our Astronomical Column

THE ABSORPTION OF LIGHT IN OPEN STAR CLUSTERS —Dr P ten Bruggencate in the *Zeitschrift für Physik*, October 31 describes an investigation of the colour indices of stars of the open clusters N G C 1647 of Præsepe and of the Hyades and deduces that these clusters consist almost entirely of dwarf stars as is to be expected on the assumption that they have developed from globular clusters and are of great age Colour brightness diagrams were prepared in which the catalogued stars were plotted and with certain assumptions as to the value of the parallax graphs corresponding to the stars of the general stellar system as determined at the Mount Wilson Observatory and described by Seares were drawn on the same diagrams It was found that in neither case did the stars of the cluster agree with the graph This was also true of the colour brightness diagram of the Pleiades which has already been described by the author

In the case of N G C 1647 an analysis of the diagram leads to the conclusion that the abnormal distribution of the stars in it is due partly to the assumed parallax being too large and partly to absorption due to extensions of the dark nebulosity in Taurus which lies between the cluster and the earth In the case of the two other clusters and of the Pleiades there is general absorption due to nebulosity inside the clusters The Pleiades form a younger cluster than the others which contains a number of A and F stars, and the nebulosity in it is bright and connected with the bright stars being formed from material recently given off by these stars, which are in an unstable state of development In Præsepe and the Hyades the clusters are older and the internal nebulosity has become dark

No nebulosity is found in globular clusters which are relatively young the stars not having reached the stage of development mentioned above the first sign of instability in these clusters is the occurrence of variable stars These and the super giants develop to O type stars and planetary nebulæ, and it is to be expected that the remains of these nebulæ will be found in old star groups or open clusters

OBSERVATIONS OF ALGOL VARIABLES —An important paper by Col F E Markwick (B A A Journal vol 35 No 2) contains discussions and light curves of six Algol variables from observations by himself and other members of the Variable Star Section They are a good example of the useful results that can be obtained in this field by careful and long continued visual estimations of magnitude The curves for three of the stars show secondary minima U Ophiuchi loss of light at secondary minimum 0 2 mag RW Tauri 0 2 mag / Vulpeculæ 0 1 mag They did not succeed in detecting the secondary minimum of Algol but the curve of principal minimum is shown in great detail The total number of observations used is 2630 they begin in 1906 for most of the stars 1899 for Y Cygni The period found for Algol is 2 867265 days which is 3 9 sec shorter than that given by Chandler The range of the observations used is 5336 days or 14 6 years The commencement and end of the principal eclipse are more rounded than those on Stebbins s curve The effect is to make the total duration of eclipse 14·09 hours which is longer than is generally given but Col Markwick defends his curve on theoretical grounds

Research Items

HUMAN REMAINS FROM ANCIENT GOLD MINES IN RHODESIA.—In view of the conflicting interpretations of archæological evidence in Rhodesia any human remains to which any degree of antiquity can be attributed are likely to be of importance for the early racial history of that area. Considerable interest therefore attaches to a report by Sir Arthur Keith on two skeletons from ancient gold mines which appears in Vol. xxii. of the Proceedings of the Rhodesian Scientific Association. The Que que skeleton was found 4½ ft. below the surface in a filled in working. It is represented by numerous fragments all weathered, partly dissolved and fallen into pieces. They are only lightly mineralised, yet have the appearance of having been buried for a considerable time, possibly a thousand years or more. Such characters as can be recognised indicate a young female of about 18 years of age, of an estimated height of 5 ft. 1 in., and belonging to the negro race. The second specimen, from Belingwe, is a pure negro type, male, between 20 and 30 years of age. The skull is small, length 182 mm., breadth 124 mm., index 68, cranial capacity 1220 cc. A remarkable feature is the projection of the alveolar bone 9 mm. beyond the nasal spine and its wide simian nasal grooves. The skull is mineralised to a certain extent and somewhat more ancient than the Gwanda woman (described in the Proceedings of the Rhodesian Scientific Association, Vol. xxi.), whose stature has now been calculated as 4 ft. 9 in. These measurements are comparable with those of two skeletons of ancient man from Rhodesia described by Dr. F. C. Shrubsall in *Man* in 1909. Thus all the remains we have from ancient ruins or mines in Rhodesia are of the Negro or Bantu type, and show no trace of Arab, Egyptian, Bushman or Hottentot strain.

PALÆOLITHIC INDUSTRY IN NORTHERN CHINA.—T. de Chadin and F. Licent (Bull. Geol. Soc. China, iii., 1924, p. 45) record the discovery of palæolithic floors at three different places in Inner Mongolia. The floors are found at the base of the Loess and in the Loess itself, and the associated mammals include rhinoceros, hyena, gazelle, antelope, horse, bison, elephas, etc. The implements are made of quartzite, psammite and silicified limestone, and appear to be of Mousterian or early Aurignacian type. In the same regions in which palæolithic implements are found in the Loess, evidence of neolithic man is shown by the presence on the surface of the earth of polished axes, arrow heads, knives and borers.

VITALITY OF JELLY FISH.—It is a remarkable fact that many of the lower animals are able to live for a long time without food, maintaining themselves during the period of starvation at the expense of their own tissues and not merely by means of reserve stores of fat or other substances. A very interesting case of this kind is described by Messrs. de Beer and Huxley in the *Quarterly Journal of Microscopical Science* (vol. 68, part 3). They found that the common jelly fish *Aurelia aurita* can be kept alive without food in laboratory aquaria for as much as thirty-eight days, during which time they undergo a progressive decrease in size, accompanied by loss of morphological and histological differentiation. The bell begins to shrink first, the oral arms later. Tentacles and thread cells disappear, and the gastro-vascular cavity closes up, the final result being a very small shapeless mass. The bell continues its pulsations until an advanced stage of the process has been reached. It will come as a surprise to many naturalists that such a delicate organism as Aurelia can remain alive for so long under such unfavourable conditions.

THE BORING MECHANISM OF TEREDO.—The manner in which the ship-worm bores into timber has been a matter of conjecture and dispute among naturalists for at least two centuries. Some have supposed the soft fleshy foot to be capable of rubbing away the fibres of the wood, perhaps with the help of a solvent or softening secretion; others have regarded the valves of the shell, with their file-like rows of teeth, as the instruments of boring. It has been reserved for Mr. R. C. Miller (Univ. California Publ. Zool. xxvi., No. 4, pp. 41, 8o, 4 pls.) to give what appears to be a conclusive answer to the question. After a detailed account of the structure of the shell, the foot and the muscles connected with them, he discusses the possible methods of boring that have been suggested. He points out that the foot is covered with columnar epithelium becoming glandular and ciliated near the edges and obviously unfitted for abrasive action. The possibility that some solvent enzyme may be secreted is not altogether excluded, although an analysis of shavings from the inside of the burrow showed no significant difference in composition from sound portions of the same block. The presence of tool-marks—scratches corresponding with the serrations of the shell—on the inside of the burrow, which has often been denied, is admirably demonstrated by a series of photographs. Finally, by laying bare the inner end of the burrow and sealing a cover glass over the opening, the author succeeded in watching the Teredo at work. It was found that the movements of the animal in the burrow were effected chiefly by means of the suctorial and surprisingly mobile foot. Boring was seen to be accomplished by rhythmical movements of the valves of the shell, which were held in position by the combined action of the foot attached to one wall of the burrow and the dorsal fold of the mantle pushing against the opposite wall.

THE CHANGING COLOUR OF THE MINNOW.—The minnow (*Leuciscus phoxinus* sive *Phoxinus lævis*) is one of those species of fish in which the male in the breeding season assumes brighter colours. Mr. Leo Abolin's communications (Beeinflussung des Fischfarbwechsels durch Chemikalien. Pt. I. Infundin- und Adrenalinwirkung der Melano- und Xanthophoren der Elritze. Pt. II. Annahme männlicher Erythrophoren-färbung durch das infundibulisierte Weibchen der Elritze. Nos. 119 and 120 *Mitteilungen aus der Biologischen Versuchsanstalt in Wien, Zool. Abt.* under the direction of H. Przibram) give a most interesting explanation of the mechanism by which this is brought about. From the first paper we learn that the colour of the fish is mainly due to black and yellow pigments contained in cells termed melanophores and xanthophores respectively. These cells are situated in two layers of the skin, a deeper and a more superficial. Injections of minute doses of weak solutions of adrenalin contract the melanophores and cause the fish to assume a pale yellow colour, the effect passes off in about two hours. Injections of similar doses of post-pituitary extract cause expansion of the melanophores of the under layer and of all the xanthophores. The grey colour of the fish becomes greenish and the belly, which is normally silver, becomes golden yellow. If the fish is blinded the injection causes intense expansion of the melanophores in the sensitive regions of the body (the lips, gill-covers and the sub-branchial region of the head), but the xanthophores do not expand. The same

result is obtained if the sympathetic system is destroyed only in this case both layers of melanophores are expanded and the xanthophores are contracted in fish which lie on a dark surface the same result follows under normal conditions From the second paper it appears that in the superficial layer of the skin on the lips the bases of the fins and on the belly there is contained a certain amount of red pigment embedded in cells termed erythrophores When the male becomes ripe these erythrophores become widely expanded as do the melanophores and xanthophores This same result can be obtained in ripe females and in small unripe males and females in which no trace of red is externally visible by the injection of somewhat strong doses of post pituitary extract (one tenth per cent) It is therefore obvious that the bodies of males and females so far as pigment is concerned have the same structure and that the secondary sexual characters of the male are due to the action of the distinctively male hormone on this common groundwork

YEASTS FATS AND ALCOHOL FROM SEAWEED — We have recently received from Prof Nadson of the Principal Botanical Garden Leningrad a short type written communication from which it appears that the possibility of the commercial utilisation of sea weeds is at the present moment occupying the attention of Russian chemists The paper in question is entitled Seaweeds as a Source of obtaining Yeast Fat and Alcohol and contains a brief summary of the results obtained by Prof Nadson working in collaboration with Messrs A G Konokotina and G K Burgvitz The authors claim to have succeeded in growing both bakers and brewers yeasts (of the type of *Saccharomyces cerevisiæ* I Saatz Frohberg etc) upon autoclave extracts of *Laminaria saccharina* and from the results obtained they conclude that it should be profitable to produce compressed bakers yeast and dry Nährhefe of high protein content in this way They have moreover apparently succeeded in producing an abundant growth of fat yeast *Endomyces vernalis* Ludw upon minced and boiled *Laminaria saccharina* cultures kept at 6 8° C for sixteen days are stated to have produced a yield of 6 22 per cent of fat upon the medium as compared with a normal content of only 0 3 to 1 per cent of fat in the untreated weed On the strength of these results the authors recommend the use of seaweed as a substrate for the production of fat for technical purposes The authors further state that they have produced alcohol from a decoction of *Laminaria saccharina* prepared by soaking 5 per cent of finely ground material in water for 12 14 hours and sterilising at 110° on this they have grown three different kinds of yeast (1) Strains of *Saccharomyces ellipsoideus* Saatz and Frohberg (2) yeasts isolated from fermenting sugar beets—*Saccharomyces betæ* and (3) torula isolated from the surface of the living *Laminaria saccharina* of Murman No data are given as to the yields of alcohol obtained but it is claimed that the distillation of alcohol from algæ gives several valuable by products The information supplied in this communication is scarcely sufficient to carry very much conviction The object of the publication may be best stated by quoting the authors own words We are giving the results obtained by us in order once more to direct attention to the sea weeds of Russia as one of her natural riches awaiting their utilisation

CRETACEOUS FAUNA AND FLORA OF SHANTUNG — An extensive series of freshwater deposits formed in a continental basin in Shantung is described by H C Tan (Bull Geol. Survey of China No 5 pt. 2 1923) and is believed to be mainly of Cretaceous age Numerous fossils have been found in the deposits and furnish interesting evidence of the plants and animals which during a long period of time lived on land or in fresh water They include dinosaurs, fishes freshwater molluscs such as Unio Leptesthes Cyrena Bithinia and Valvata insects belonging to the orders Orthoptera Blattoidea Coleoptera Odonata Lepidoptera Diptera etc The plants are mainly conifers and cycads Descriptions and figures of some of the molluscs and insects are given by A W Crabau

SOMERSET OIL SHALLS —Messrs H G Shatwell A W Nash and J I Graham recently communicated an account of the Somersetshire oil shales to the Institution of Petroleum Technologists These shales outcrop for about ten miles along the coast in the vicinity of Blue Anchor and extend inland for a distance of one to three miles They form part of an argillaceous and calcareous group of sediments which have been assigned to Lower Lias and Rhætic horizons and their mode of occurrence is in two basins lying on either side of the Devonian Quantock Hills the larger basin (Lilstock Basin) being situated on the east the smaller (Doniford Basin) on the west Bituminous shales of Lower Lias age have long been known from the opposite South Wales coast and the authors conclude that the Somerset shales are a continuation of these The Somerset shales occur in beds varying from 1 to 20 feet in thickness those of South Wales being much thinner 6 inches to 5 feet Proximate analyses of the Somerset shales show that they have an average specific gravity of 2 4 from 70 to 73 per cent of ash 3 5 per cent of moisture 23 to 28 per cent of volatile matter (less water) 1 70 to 4 52 per cent of sulphur and 13 to 17 per cent of carbon dioxide The specific gravity is higher than the Scottish oil shale which averages 2 0 while the high carbonate content is unusual Results of assays and steam distillations carried out by the authors show that the yield of oil from one ton of shale is about half that of the average yield from the same quantity of Scottish shale the total amount obtained from the Somerset shales varied from 5 00 gallons to 10 4 gallons ammonium sulphate from 4 to 6 lb and gas from 1200 to 1900 cubic feet per ton The crude shale oil has an average specific gravity of 0 939 and sulphur content up to 3 12 per cent it is dark brown in colour and has a less sweet odour than that distilled from Scottish shale On fractionation naphtha (specific gravity 0 807 to 0 852) kerosene (0 888 to 0 925) and heavy distillate (0 973) are obtained distillate above 300 C failed to yield more than a trace of paraffin wax From the above details it will be gathered that the Somerset oil shales notwithstanding the comparatively low sulphur content of the oil obtained from them do not inspire confidence from a commercial point of view

RAINFALL IN MYSORE —The Meteorological Department of the Mysore Government has issued a Report on Rainfall Registration for 1923 prepared under the supervision of Mr C Seshachar the Meteorological Reporter There were 226 stations gauging rainfall during the year The greatest rainfall on any one day was 17 90 inches at Agumbi in the Shamoga District on August 7 the heaviest record in 1922 was 22 16 inches at the same station In the Kadur District the heaviest fall in 24 hours was 16 85 inches at Bijrapur Estate on July 24 and in the Hassan District at Marnhalli toll gate the fall in 24 hours on August 14 was 11 43 inches In no other District did the fall in 24 hours amount to 5 inches July was the wettest month on record since 1893 the year in which the

Meteorological Department was organised; the monsoon was unusually active in the western parts of the State. A monthly total of 202 inches was recorded at Byrapur Coffee Estate against a normal of 106 inches. The south-west monsoon period, June to September, was generally wet, the total rain over the State being 26 per cent above the normal. The north-east monsoon period, October to December, was the driest on record since 1893. The deficiency varied from 66 per cent in the Mysore District to 89 per cent. in the Chitaldrug District. The seasonal aggregate for the State was 1·95 inches against a normal of 8·04 inches, which is 76 per cent. in defect of the normal. The largest annual total for a single station was 393·64 inches at Agumbi in the Shamoga District, and the smallest was 4·36 inches at Dharmapur in the Chitaldrug District. Rainfall maps are given, which help much to a complete understanding of the work.

A Shunted Grassot Fluxmeter.—A Grassot fluxmeter may be described as an over-damped moving-coil ballistic galvanometer having practically no controlling force. This instrument is of great value for measuring magnetic flux. Gisbert Kapp, in his book on "The Principles of Electrical Engineering," suggests the possibility of increasing the range of the instrument by using a shunt, but he gives neither the theory of how it would work nor the formulæ that would have to be used with it. In April 1924 Masamiti Sase read a paper to the Physico-Mathematical Society of Japan in which he gives the complete theory of the multiplier, and gives experimental results confirming it. In the instrument he used, the highest permissible value of the shunt was about 8 ohms, which was about one-third of the resistance of the fluxmeter. He shows that it is desirable to use a shunt of manganin wire having the highest allowable resistance. His results prove conclusively that the particular Grassot fluxmeter with which he experimented could be used with a shunt of 8 ohms even when the highest accuracy is required. This greatly increases the range of the instrument.

The Evidence of the Proof Plane.—Mr. J. Clark, writing from Kewanna, Manitoba, directs attention to a method of dealing with observations made with the proof plane. When such a plane, without electrical charge, is introduced into the electrostatic field surrounding one or more conductors, one at least of which is charged, it will have, at each point in space, a definite potential V_p, depending on the external charges and the equal charges of opposite signs induced upon it. This potential Mr. Clark calls the potential of the free charge of the proof plane. If, then, the plane is brought up to a large insulated conductor, the total charge of which is zero, without actually making contact with it, the potential V_p will, in general, differ from the uniform potential V_c of the conductor, being greater than V_c on one side of the conductor and less on the other. If now the plane is made to touch the conductor, electricity will flow from the plane to the conductor in the first position, and from the conductor to the plane in the second, so that when the plane is removed from the field, and brought to an electroscope, it will be found to have a negative charge in the first case and a positive charge in the second. It is not always possible to regard the proof plane as temporarily forming a part of the surface which is being tested, since this is often curved, and the method suggested will often prove valuable.

A New Diamagnetic Phenomenon in Gases.—An investigation of the diamagnetism of hydrogen, nitrogen and carbon dioxide, at different pressures, is described by Dr. A. Glaser in the *Annalen der Physik* for October. A rod of diamagnetic lead glass was suspended inside the experimental tube containing the gas, by a 2-5μ quartz thread attached to a torsion head. Thin threads of paramagnetic cobalt glass were melted on to the rod, so that the whole became slightly paramagnetic. The tube was surrounded by a water jacket by means of which the temperature was kept constant to within 0·01° C. In each observation the torsion head was twisted to bring the light spot to zero. As the pressure was diminished the susceptibility at first diminished in proportion; but in each of the gases this ceased to be the case at a pressure which depended on the nature of the gas and the intensity of the field. Thereafter the rate of diminution of susceptibility with pressure diminished greatly for some time, and in the end, at low pressures, the susceptibility was three times as great as it would have been if the original rate of diminution had been maintained throughout. It is suggested that, at low pressures, the distance between the molecules is such that there is time between collisions for them to become oriented with respect to the field. At higher pressures the collisions are constantly destroying any tendency to orientation which may be produced, so that all the molecules are practically unoriented.

A New Lead Accumulator.—In the *C.R. Acad. Sci. Paris*, November 24, M. C. Féry describes a lead accumulator which does not sulphate, even if discharged and left uncharged for two years, at the end of which time it can be recharged in the ordinary manner. The author has previously shown that the true reaction taking place in the Planté cell is given by the reversible equation,

$$Pb_2 + H_2SO_4 + Pb_2O_5 = Pb_2SO_4 + 2PbO_2 + H_2O,$$

and that $PbSO_4$ is only formed accidentally when the cell becomes "sulphated." Pb_2O_5 is a black peroxide, and Pb_2SO_4 is greyish black in colour. The spontaneous discharge of the Planté cell is due to the combined action of the electrolyte and of oxygen on the negative plate, according to the equation

$$Pb_2 + H_2SO_4 + O = Pb_2SO_4 + H_2O,$$

and this action may develop into

$$Pb_2SO_4 + H_2SO_4 + O = 2PbSO_4 + H_2O$$

if the cell is left undischarged too long. To avoid this, the author places the negative plate at the bottom of a deep glass jar, and separates it from the positive, and from the air, by a porous material containing the electrolyte. A figure in the original paper shows the cell as it appears when partly discharged, with a layer of black plumbous sulphate on the upper surface of the negative plate. A cell left without recharge for twenty-six months only lost 66 per cent. of its original charge, the loss in the first month being 4 per cent., 83 per cent. of the original charge remaining after four months, while an ordinary cell would have lost the whole of its charge in this time.

Erratum.—In Nature of December 20, p. 909, in a paragraph on the "Cytology of Cotton," referring to the work of Mr. H. J. Denham, it is suggested that the reason for the appearance of Mr. Denham's papers in the Journal of the Textile Institute as well as in the *Annals of Botany* is the importance of the work to the cotton-growing industry of the British Empire. We learn that the work referred to was carried out at the laboratories of the British Cotton Industry Research Association, and permission to publish it in the *Annals of Botany* was given on the understanding that, in common with all papers from the Association's laboratories, it would be published in the Journal of the Textile Institute.

The Japanese Earthquake of 1923

MR K SUDA of the Imperial Marine Observatory at Kobe has recently issued a detailed and interesting report on the great Japanese earthquake [1] It is based on an examination of all the seismograms obtained at Japanese observatories and on an exploration of the central tract from September 19 to October 12 The following is an abstract not of the whole memoir but of those portions which have not been fully treated in earlier papers [2]

It is not often that isochronal lines (the coseismal lines of Mallet) can be drawn for any earthquake The large number of earthquake observatories in Japan and the radio time service have enabled Mr Suda to give a series of such lines certainly the most accurate of any yet attempted They are drawn for every ten seconds except towards the north east From the epicentre to a distance of 200 km the curves are extremely irregular Beyond this distance they become portions of nearly concentric circles and the distance between successive curves increases with the distance from the origin The curves in the north east of Japan are packed more closely together than in the south west The irregularity of the curves is due partly to geological conditions partly to the form of the focus

On the same map are shown the initial directions of the shock These are not always directed towards or from the epicentre small deviations being experienced at several places due chiefly perhaps to the geological structure of the country The initial motions are condensational (or from the origin) at nearly all the observatories to the south west of the line from Matsumoto to Kofu Between this line and that from Niigata to Fukushima (that is in the region including the central zone) condensational and rarefactional movements are mixed together To the north east of the latter line the initial motions are again with few exceptions condensational The complexity in the intermediate region may be connected with the nature of the displacement that caused the earthquake The directions of initial motion are usually normal to the isochronic lines Smoothing off the local variations in these lines the space time curve is drawn It cuts the time axis at a point corresponding to 11 h 58 m 26 s the time of occurrence at the epicentre considered as a point The velocity of the primary waves near the epicentre was 5 5 km per sec that of the large waves was constant and about 3 59 km per sec

One more result obtained from the study of the seismograms may be referred to The angle of emergence at Kumagaya was 21° and at Choshi 13 5° At Mera the epicentral distance is 46 km and the focal distance (as determined by the duration of the preliminary tremor) 70 km ; at Tokyo these distances are 82 km and 98 km The focal depths given by these four observations are about 50 35 54 and 55 km the average being 48 km

Mr Suda adds some interesting details about the changes of level along the coast of Sagami Bay Since the earthquake, the land has shown a tendency to return to its original level For example, at Misaki (near the end of the Miura peninsula) the elevation on September 1 was about 760 cm and the sea bed between it and a small island in front was laid bare On September 5 the land here began to sink at first at the rate of nearly 60 cm a day then more slowly until on September 26 the uplift was only about 140 cm Similarly at Tateyama at the end of the Bo-so peninsula the uplift on September 1 was 220 cm Later in the same month it was reduced to 140 cm The first upheaval and the subsequent sinking were both most marked at the ends of these peninsulas There is also evidence that at both points the land had been slowly sinking for many years before the earthquake At Shitsura near the end of the Miura peninsula the land had sunk about 2 metres during the preceding sixty years and some of the farms near the shore had become covered by the sea After the earthquake the land was restored to its former level The remarkable changes of level in the floor of Sagami Bay have been referred to in NATURE (vol 113 pp 473 474) The first soundings were made soon after the earthquake They have since been repeated with great care and a comparison of the two maps reveals no great differences The *tsunami* or seismic sea waves were comparatively low The greatest height attained was 11 metres at Atami where 155 houses were washed away and about 60 persons were killed Mr Suda attributes the small height of the waves in part to the upheaval of the land round Sagami Bay

One of the most interesting chapters in the memoir is that on after shocks Omori had found empirically that the decline in frequency of after shocks follows a hyperbolic law The theoretical investigation by Prof S Kusakabe shows that the decline takes place according to a logarithmic law of which Omori's law is a particular case and that the frequency-curve approaches or deviates from the hyperbolic form according as the time during which the stresses causing the earthquake act is long or short As the curves for different observatories are nearly hyperbolic it follows that the great earthquake was tectonic and not volcanic in origin Mr Suda however points out a remarkable feature in all the frequency curves whatever the distance from the epicentre From the first to the third days the curve is hyperbolic and after the fourth day again hyperbolic but with a lessened value of the constant For example at Kumagaya the frequency curve is at first represented by the equation $xy = 327$ but after the fourth day by the equation $xy = 242$ Mr Suda infers that the stresses that caused the earthquake began to operate again after three or four days and that in consequence the frequency of after shocks was distinctly less after this time He suggests that these districts will probably be visited periodically by great earthquakes until the stresses causing them are changed

The after shocks are divided by Mr Suda into two classes which he calls the Sagami Sakawa family and the Bo so family the former occurring in an area to the west of a north south line passing just to the east of Oshima and the latter in an area on the east side After shocks of the Bo so family were usually stronger than the others and had a longer vibration-period The greatest of the Bo so series was that on September 2 at 11 h 47 m which was nearly as strong as the great earthquake The epicentre lay off Katsuura on the Pacific side of the Bo so peninsula and the first displacement within the focal region occurred in a vertical plane for the initial motion at every observatory near the epicentre was directed outwards Mr Suda points out an interesting relation between the frequency of the after shocks generally and the atmospheric pressure the rate of pressure change and the pressure gradient The frequency is slight or great according as these conditions are the same as or contrary to those which prevailed on the day of the earthquake

The theoretical portions of Mr Suda's memoir interesting as they are must be passed over more

[1] Mem. Imp Marine Obs. Kobe Japan vol 1 1924 pp 137-239 tables 1-49, and 38 plates.
[2] NATURE, vol. 113, pp. 234, 473-474 vol. 114, pp 70 202, 484

rapidly. He considers that there were two epicentral zones, one directed north-north-east in the central part of Sagami Bay, the other intersecting it and directed north-west. The former coincides with the great region of subsidence in the bay, and this subsidence produced the condensational initial motion around the epicentre. Beneath the second epicentral zone, he thinks, there was a horizontal sliding of a layer of the crust towards the south-west, which would produce condensational motion on the south-west side and rarefactional motion on the north-east side. The vertical displacement beneath the first zone being the more important, the condensational initial motion prevailed at some distance from the origin. Among the secondary causes of the earthquake Mr. Suda includes the typhoon which was passing over the northern part of the epicentral region at the instant when the earthquake occurred. C. D.

Italian Theses on Chemistry and Physiology.

THE twenty-sixth volume of reports, recently issued by the Cagnola Scientific Foundation, covers the period 1917–1923 and deals with the essays on various scientific subjects submitted for adjudication to committees appointed by the Royal Lombardy Institute of Science and Literature. The subjects vary widely in character, but are all of medical or chemical interest. In a few instances only have the theses presented been deemed worthy of reward, and of the successful theses, four only are printed *in extenso* in the present volume.

In "The Chemio-therapy of the Spirilli," which extends to over 160 pages and is accompanied by many plates, diagrams, etc., Prof. Giorgio Castelli gives, in addition to a succinct account of previous knowledge of this subject, the results of his own numerous experiments, which lead to various important conclusions. The slight increase in the efficacy of the curative agents determined by prolonged contact of the latter with the air during the manipulation is insufficient to compensate for the dangerous increase often observed in the toxicity. Oral administration of the arsenobenzenes is not to be recommended, and the use of dimethylaminotetraminoarsenobenzene, proposed by Giemsa, is not only less effective than that of salvarsan or neosalvarsan, but is also followed by more frequent and more ready relapse. Increased toxicity is also against the employment of compounds obtained by the introduction of amino and other nitrogenous groupings, sulphur, etc., into the molecule of arsenobenzene. In some cases augmented therapeutic efficacy is attained with compounds of salvarsan with silver or copper salts, but here too the frequency of undesirable after-effects militates against the application of such compounds on a large scale.

Prof. Aldo Perroncito, in a short contribution on the derivation of blood platelets, demonstrates the possibility of the formation of new platelets independently of the elements of all other tissues of the organism. In blood drawn from the jugular vein of the cat or dog, and treated with sodium citrate to render it non-coagulable, and then with pyrodin solution, the number of the platelets becomes doubled or, in some instances, even quintupled after the blood has been kept at 38° C. for about an hour. Exclusion of the intervention of either the corpuscles or the plasma leads to the conclusion that the platelets are capable of reproducing other elements with similar morphological characters.

In his memoir entitled "Catalytic and Enzymic Phenomena," occupying 130 pages and including a very useful bibliography, Prof. Ugo Pratolongo develops a novel interpretation of recent results arising from modern mechanico-static theories of chemical phenomena. He has succeeded in distinguishing in chemical kinetic equations the terms depending on piezometric actions and on medial actions from terms proper to the mechanism of the reaction. The application of this principle to well-known accelerating reactions shows that some of these are definitely catalytic in nature, inasmuch as a change in the mechanism of the chemical reaction, and hence in the critical energy relative to the reaction, is involved; others are of medial character, and others again—heterogeneous catalyses—possibly depend on variations in the active concentration of the reagents induced by the catalyst. The experimental results show that, in the decomposition of hydrogen peroxide, the critical energy assumes values depending strictly on the metal functioning as catalyst and independent both of its method of preparation or state of subdivision and also of the presence of activating or inactivating agents. Thermal inactivation of a catalyst consists of partial destruction of the catalyst, the remaining fraction retaining its activity unaltered.

Under the title "Interchange of Hæmoglobin in Physiological and Pathological Conditions," Dr. Enrico Greppi discusses the different factors operative in the continual destruction (hæmolysis) and reformation (hæmoglobinogenesis) of the blood-pigment.

Astronomical Observations at Greenwich and the Cape.

THE first impression on seeing the annual volume for 1921 of "Greenwich Observations"[1] is its thinness in comparison with the volumes of two or three decades ago. It appears to be the least bulky in the last hundred years. This is due to a reduction accomplished during Sir Frank Dyson's tenure of office by the suppression of much of the detail of the observations, but enough is still given to show the data on which the tabulated observations depend.

The results are given concisely and orderly, and they represent an immense amount of routine work which is carried on from year to year at Greenwich, a work never in the limelight but, on its astronomical side at least, the basis for the discussion of all the problems of fundamental astronomy.

The observations with the Transit Circle take up the first section, and show the state of adjustment of the instrument from day to day, and then give the observations of right ascension and declination of the sun, moon, and planets, together with the observed errors of the tabular place as given in the Nautical Almanac. More than 17,000 observations were made in connexion with the Transit Circle in the course of the year. The observations of the moon have been combined with the extra-meridian ones taken with the Altazimuth, and give the error both of the Nautical Almanac (Hansen's tables with Newcomb's corrections), and Delaunay (Connaissance des temps,

[1] Astronomical and Magnetical and Meteorological Observations made at the Royal Observatory, Greenwich, in the year 1921.

Radau's tables). It is of interest to note that the latter corrections are much the smaller

The observed errors of the wireless time signals received from Paris, Nauen, and Annapolis are shown in Table IV. (p. A 16). The range of error, from about 0·2 sec. early to 0·4 sec. late for each of the three observatories, is rather large when the installations for determining and keeping time at the observatories concerned are considered The observations, however, have not been corrected for errors in the sending It is not stated to which series of morning signals the Paris observations refer, and it would be of value to any one discussing these results to know whether the beginning, middle, or end of the signal was referred to the local clock beat

The next section deals with the measures of the photographs of the sun taken at Greenwich, the Cape, Kodaikanal, and Dehra Dun Thanks to this co-operation, photographs were available for each day of the year. There is a pronounced decline in the mean daily area of spots, corrected for foreshortening, from 1052 (1919), 618 (1920), to 420 (1921) Similar figures for the faculæ are 1729 (1919), 1219 (1920), to 739 (1921), the unit being the millionth of the sun's visible hemisphere The last section gives the usual details concerning the magnetical and meteorological observations These form about one-third of the whole volume. Plates show the magnetic disturbances for three consecutive days, May 13, 14, and 15

In one respect the title, "Greenwich Observations, 1921," does the book less than justice Except in the annual report at the end of the volume, there is, for example, no mention of the work done with the Thompson Equatorial, with which more than 1000 parallax plates were taken, and almost as many measured There is no question that the national observatory at Greenwich continues to maintain its high standard of duty and performance, though one may require to read between the lines to prove it

The Cape portion of the Astrographic Chart and Catalogue extends from declination $-40°$ to $-52°$ The volume of the catalogue now issued [1] is the eighth of this series to appear The previous members, numbers I.-VII., give the measures in the seven zones from $-41°$ to $-47°$, the first appearing in 1913, and the last in 1923.

The present volume was delayed in printing, apparently by the War, for the introduction was signed by the late Mr S S. Hough in 1916 It contains the measures of the rectangular co-ordinates of all the stars shown on the plates having their centre on the declination circle $-50°$

The introduction gives a short description of the telescope, the method of measurement of the plates, the process followed to guard against errors in the measuring, and the further checking of the results by the intercomparison of overlapping plates It is evident that great care has been taken to eliminate errors

The plates were exposed during the years 1902–1908 and measured with two exceptions between November 1907 and September 1908 The catalogue gives the measures of the x and y co-ordinates to 0·001, an estimation of the diameter of the image, together with the identification by number and magnitude of the star in the Cape Photographic Durchmusterung, if it occurs in that catalogue No attempt is here made to convert these estimates of stellar diameter into a standard scale of magnitude.

The catalogue proper consists of 465 pages, with a total of 79,105 stars, or a distribution for the first 12 hours of R.A of 32,504 and for the last 12 hours of 46,601

[1] Catalogue of Rectangular Co-ordinates and Diameters of Star Images derived from Photographs taken at the Royal Observatory, Cape of Good Hope Zone $-50°$

Annual Meeting of the Geographical Association.

THE annual meeting of the Geographical Association was held at the London School of Economics on the first three days of January The gathering was remarkable for an extraordinarily valuable series of papers of high scientific worth, for a broadcast message by Prof J. L. Myers, the president, and for a continuation of the plan of inviting a distinguished continental thinker, in this case Dr A Sommerfelt, of Oslo, to speak

In his presidential address, Prof Myers dealt with the historical method in ethnology and with cogent argument and gentle banter criticised the conclusions of some investigators, especially Mr Perry, who, applying the hypothesis of long distance diffusion of culture, announced as discoveries speculations which recalled extreme conclusions of Max Müller on the Aryan Race or those of the Anglo-Israelites on the lost tribes

Among the other papers two stood out as remarkable One was entitled on the programme "Life among the Hill Tribes of Algeria." It cannot be described satisfactorily either as a description illustrated by films or as films with appropriate comments, for the first of the noteworthy points just was that it was a coherent whole in the sense that the words and music of a good song are coherent The kinema was in fact seen at its best as an educational instrument of the highest class. It is not easy to make it so, but that it can be done is evident. The second point is that what was done was worth doing. The films were thoroughly scientific, extremely human, entirely free from anything meretricious and yet extraordinarily interesting. They are the property of Mr J A Haeseler, who is collecting a scientific library of such films, and they had been taken with the help of Capt Hilton-Simpson, who gave the address They showed the actual life of the people basket-making, shoemaking (with platted grass), making of wooden door-locks with an adze strikingly like a bronze age tool, quern-making and corn grinding, ploughing, skinning a goat and the processes by which the skin is turned into a water-bottle, and bread-making, but perhaps the most fascinating of the pictures were those showing the fundamental arts of textile and pottery making Spinning was exhibited as carried on by two or three of the simplest possible methods, one even without the aid of a spindle, while two types of simple looms, and the entire operation of weaving from the making of the warp and setting up of the loom to the final process of inserting the woof, was shown with wonderful clearness So also clay was obtained from a pit, freed from stones, and a pot gradually built up before one's eyes without—and this is the remarkable fact—the aid of the potter's wheel The ornamenting of the pot, the firing, the fire being lit by a boy, and the glazing of the still hot vessels were equally clearly shown

The performance—it is difficult to find a satisfactory word for the combined appeal to eye and ear—gave an insight not only into the geography of another land, but also into conditions of a long past time very thinly veiled by later growths and accretions We have said that the kinema was seen at its best This was because it was used for what it is best fitted. It was used to show things as they happened,

dynamically, not statically. We might perhaps qualify our statement and say "almost at its best" It would have been better, though impracticable, to show several of the films again. Even when one knew what to look for, it was quite impossible to follow all the details of what was done. Further, it was obvious that while for exhibiting processes the film is the superior, yet for still life and for analysis the slide has still the advantage

The other paper was by Mr C E P Brooks and was entitled "The Climatic History of the Fiord Countries" Climatology is still in its infancy, and this is one of the few papers which deal with climatic, as distinct from meteorological, problems without becoming unintelligible amid a maze of statistics Mr Brooks traced out the succession of climates during and since the Ice Age, if indeed we are out of the Ice Age He suggested that the Daun stadium should be dated round about 1800 B C rather than 5000 B C , and estimated the temperature of the Norwegian coast at 5000 B C to have been 4° higher than at present His most striking suggestion related to the causes of these climatic changes He associated them with variations in the ice conditions in the Arctic Ocean Analysis of these conditions by Kerner Marilaun and himself has shown that the Arctic floating ice-cap must either have its present extent or the whole ocean must be free of ice, no intermediate stage being stable. He related the voyages of the Norsemen, who in their voyages to the south of Greenland mention storms but never ice, and the great Asiatic migrations, to an open period in which the Arctic was unglaciated, and concluded, "In the twelfth century the glacial stage recurred and has apparently persisted to the present day" So we are still in the Ice Age!

Periodicals in Canadian Libraries.[1]

THE need for co-operative library catalogues of scientific periodicals has long been felt in many countries, and various projects have been undertaken to supply the deficiency The work before us is an attempt to provide for those specially interested in scientific periodicals, and consists of a list of such material available in Canadian libraries, together with bibliographical information Journals are arranged under their latest form of title, and publications of academies under the name of the society or institution In our opinion, this method of listing the publications of academies does not facilitate their ready identification Under the words "Kaiserlich" and "Koniglich" there are quite a number of entries, although events of recent years have caused these adjectives to be dropped or replaced As an example, the Koniglich-Preussische Akademie der Wissenschaften is now known as the Preussische Akademie, though this fact cannot be ascertained from the present work. Had publications of this character been listed under the first word of their title—in this case Sitzungsberichte—consultation would have been simplified.

It is to be regretted that a number of Canadian libraries, whilst those responsible realised the importance of the work, were unable to include their possessions in this list The reasons given were that periodicals were not catalogued or that the staff at their disposal was inadequate. It is obvious that full advantage cannot be taken of the resources of Canadian libraries if a proportion of them are compelled to neglect the preservation and cataloguing of serials. Further, Canadian science will be under a distinct handicap until steps are taken to provide the libraries with adequate competent assistance.

Despite the difficulties confronting them, the compilers have produced a work which should prove of considerable aid to scientific workers in the Dominion, and they are to be congratulated upon the completion of a volume which bears evidence of much care and painstaking labour. Due credit should also be given to the Canadian Department of Scientific and Industrial Research, the material co-operation of which enabled the early publication of the volume.

F. W. CLIFFORD.

University and Educational Intelligence.

ABERDEEN —The Fullerton Research Scholarship in natural science has been awarded to Miss Elizabeth T Geddes.

GLASGOW —The King has been pleased to approve the appointment of Mr. James Montagu Frank Drummond to the regius chair of botany in the University, vacant by the retirement of Prof F. O. Bower. Mr Drummond took first-class honours in the Natural Sciences Tripos at Cambridge in 1904, and gained the Frank Smart Studentship for research in botany at Gonville and Caius College He became lecturer in botany at Armstrong College, Newcastle-upon-Tyne, and in 1909–1921 was lecturer in plant physiology in the botany department of the University of Glasgow Since 1921 he has been Director of the Scottish Plant Research at Corstorphine, Edinburgh During the War he served in Palestine, Egypt, and France, acting as battalion intelligence officer, and afterwards as brigade education officer His published works refer chiefly to plant physiology, but include a series of papers on the "Botany of the Palestine Campaign" communicated to the Linnean Society

LONDON —The lectures which were to have been given early this month by the late Prof J. I. Hunter at University College on "The Anatomy and Physiology of the Sympathetic Innervation of the Striated Muscle" will be delivered by Prof. G. Elliot Smith on January 19, 26, and February 2 at 5 o'clock.

The degree of Ph.D in Science has been conferred on Mr. W. Jevons (Imperial College—Royal College of Science) for a thesis entitled "Spectroscopic Investigations in connexion with the Active Modification of Nitrogen" and other papers.

NOTICE is given by the Imperial College of Science and Technology, South Kensington, of the alteration in the date of the Entrance Scholarship Examination, which in 1925 will begin on April 24. Eighteen Scholarships, value 62*l* 10*s* each, are offered, six being tenable at the Royal College of Science, six at the Royal School of Mines, and six at the City and Guilds (Engineering) College, for admission at the beginning of the session, namely, the first Tuesday in October. Prospectuses and full particulars may be obtained on application to the Registrar, Imperial College, South Kensington, S W.7

APPLICATIONS are invited by Yale University for two Theresa Seessel Research Fellowships for the promotion of original research in biological studies, each yielding 300*l*. Preference will be given to candidates who have already obtained their doctorate, and have demonstrated by their work fitness to carry on

successfully original research of a high order The holder must reside in New Haven during the college year, ranging from October to June. Applications should be made to the Dean of the Graduate School, New Haven, Conn , U S A , before May 1 next, and should be accompanied by reprints of scientific publications, letters of recommendation, and a statement of the particular problem which the candidate expects to investigate

THE Royal Technical College, Glasgow, directs attention in its report for 1923 24 to the part taken by it for many years in the further education of adults The evening classes of last session were attended by 2587 adult students of ages ranging from twenty-one to seventy-five and, in addition, 546 enrolments were received for the " Elder " lectures on astronomy by Prof George Forbes on " The Old Astronomy and the New," and by the Rev E Bruce Kirk on " Stars in their Associations " The College maintained also its press campaign for informing the public of the important part taken by chemistry in the life and industry of the country, and numerous papers of a popular character were published by members of the staff on such subjects as the utilisation of waste, chemistry and wireless, etc

FROM the University of Leeds we have received a copy of the Council's annual report for 1923 24, which was issued on the eve of the Jubilee and " Coming of Age " celebrations of December 15-20 In it the Council announces, after summarising the serious and numerous present deficiencies in accommodation and equipment and in the provision for the social and athletic life of the University, that action is being taken to meet the most pressing requirements and to make the Jubilee year a starting-point for another period of progress. That they are able to do so is due in large measure to increased local aid. Grants from local authorities during the past year amounted to 30,000*l*., not counting the fees, amounting to 4500*l*., remitted to students as a condition of such grants The other chief sources of revenue were . endowments, donations, and subscriptions, 21,000*l*., parliamentary grants-in-aid, 58,000*l*., and fees for tuition, examinations, graduation, Students' Union, etc , 60,000*l*

THE December number of *The University Bulletin*, issued by the Association of University Teachers, contains an address by the president of the association, Prof Alexander Mair, on the significance of this organisation as marking a distinct phase in the evolution of the university system in Great Britain Among the many *éclaircissements* produced by the War were, Prof Mair says, the revelation to English people that in the universities they had a *national* asset, and a clearer awareness on the part of the universities themselves of their function and destiny. A " get-together " spirit took the place of particularism, and one of the indications of this was the appearance of the Association of University Teachers At present about 75 per cent of all the teachers in the university institutions of England and Wales belong to its 25 branches, although " Oxford and Cambridge are still hesitant, and their absence makes the one (an important) gap in an otherwise continuous front." In referring to the spirit of co-operation as between universities and the recognition of their value to the nation as post-War phenomena, Prof. Mair seems to have overlooked the fact that the first Congress of Universities of the Empire took place, and the Universities Bureau of the British Empire was constituted in 1912.

Early Science at the Royal Society.

January 10, 1662/3. Mr Howard mentioned a way of roasting in a very short time, with basting the meat with flames of lard poured upon it Dr Wilkins, that of boiling and stewing meat with lamps Mr Hoskyns, that of roasting many pieces of meat with a fiery globe of plated iron standing in the middle Sir Cyril Wyche, that of keeping water and other things warm in a double pot, separated by an interstice

January 11, 1671/2. Mr Isaac Newton was elected [Newton had written earlier " I am very sensible of the honour done me by the Bishop of Sarum in proposing me candidate, and which I hope will be further conferred upon me by my election into the society, and, if so, I shall endeavour to testify my gratitude, by communicating what my poor and solitary endeavours can effect towards the promoting philosophical design "]

1664/5. Sir Robert Moray mentioned, that the King had made an experiment of cold, with three glasses filled with sweet water, used for washing, one glass bigger than the other, taken out of a trunk by the King's barber, and freezing, after they had a very little while been opened, first at the top, and then with shootings of ice to the bottom, and so congealing together

January 13, 1663/4. The president acquainting the council, that Mr Hooke had discovered to himself, Sir Robert Moray, and Dr Wilkins, an invention, which might prove useful to England, and to the world, and that he had a good opinion thereof, but that it was necessary, that some experiments should be made for farther certainty, before it was made public which would require some charges not so fit to be put upon the inventor , it was ordered, that the President, Sir Robert Moray, and Dr Wilkins have power to employ any sum under ten pounds of the society's money for the said purpose

1669/70. Mr Oldenburg produced a manuscript sent and addressed to the president by Mr Flamstead of Derby, giving an account of some of the more notable celestial phenomena of the year 1670 to be conspicuous in the English horizon, among which was an eclipse of the sun visible in England, April 9, but omitted by all other astronomers The society declared that this was a very useful labour for the improvements of astronomy , and that therefore the author should receive their thanks by the secretary

January 15, 1661/2. Prince Rupert sent the society a description in High Dutch, of the method of making good gun-powder , which Mr Oldenburg was desired to translate, and Sir Robert Moray to return their thanks to his highness

1673/4. It being moved that Dr Daniel Cox having made many observations and experiments concerning the nature and figures of all sorts of salts, might be desired to impart them to the society, he was desired accordingly, and promised, that he would do so, after he had viewed and examined such salts by such a microscope, as had been approved of for its goodness by the Society · and a microscope being brought by Mr Cock to be examined, the trial of it was referred to a fitter time, it being then candle-light

January 16, 1667/8. Mr Oldenburg mentioned that he had received advice from Paris, that the person formerly said to have undertaken the translation of the " History of the Royal Society " into French, had not yet begun it, and was willing to forbear, upon notice sent him, that there was one in London, who would perform it And Dr de Molin being the person, who had undertaken that work in England, and now present, was desired by the Society to proceed in what he had begun with all possible care and diligence

Societies and Academies.

LONDON

Aristotelian Society, December 15.—L. J. **Russell**: Science and philosophy. Scientific investigation makes use of hypotheses, but something more is needed in the search for truth. The inquirer goes to Nature with demands which his own nature enjoins on him. Demands like hypotheses are anticipations, they say more than Nature tells, but they go beyond hypotheses, for they challenge Nature. Some demands are logical, some æsthetic, some metaphysical. Only legitimate demands can be satisfied, and we can only know what demands are legitimate by explicating the universe in detail by their help. There cannot be a view which is true in philosophy and in the end unworkable in science, or a view which is true in science and untrue in philosophy.

CAMBRIDGE

Philosophical Society, December 8.—C. T. R. **Wilson** and G. I. **Taylor**: The bursting of soap-bubbles in a uniform electric field. Measurements were made of the electric field necessary to burst a soap-bubble attached to a metal plate. The half-bubble correctly represents half of a complete bubble immersed in a uniform electric field. The instability is shown by photographs to take the form of a thin thread of fluid which is drawn off from the top of the bubble. The product (electric force) × (square root of radius) is constant at the bursting point. The maximum diameter of water-drop which can exist without bursting in a uniform electric field of 30,000 volts per cm. is 0·4 mm.—E. A. **Milne**: Dissociative equilibrium in an external field of force. The conditions of thermodynamic equilibrium in a gravitational field of heterogeneous substances capable of undergoing reversible chemical reactions, which were formulated by Willard Gibbs, are extended to include the case in which the products or reactants are associated with electric charges and may be subject to an external electric field. Application is made to the high-temperature ionisation of gases in stellar atmospheres.—T. M. **Cherry**: (*a*) Some examples of trajectories defined by differential equations of a generalised dynamical type; (*b*) Integrals developable about a singular point of a Hamiltonian system of differential equations. Part II.—J. **Brill**: Note on the Lorentz group.—E. H. **Neville**: Note on the harmonic conic.—R. **Hargreaves**: Thermodynamics and quantum theory.

DUBLIN

Royal Dublin Society, December 16.—H. H. **Jeffcott**: The theory of variation of flow in pipe lines with surge chambers consequent on variation of load on hydraulic turbines operated therefrom. The surge chamber, used with long pipe lines, acts as a supplementary reservoir near the turbines, so that the demand for increased discharge consequent on increase of load can be promptly met. This avoids the delay occasioned by the inertia of the great mass of water in the pipe, which requires some time for its acceleration, and also serves to relieve the pipes from water hammer consequent on the partial or complete closing of the turbine gates on reduction of load. The surge oscillations set up in the pipe line and surge chamber must not be allowed to persist for so long as to disturb the operation of the turbines unduly, and to this end a damping arrangement is often introduced. Equations are obtained for the motion of the water in the general case corresponding to any given law of opening or closing of the turbine gates, and approximate solutions are given.—Rev. H. C. **Browne**: The influence of the Fitzgerald contraction upon distance measurements and clock times. A real, absolutely existing Fitzgerald contraction underlies the relativity contractions indicated by the Lorentz formulæ, and the entire symmetry and equivalence of all systems in uniform motion of translation depend upon this real contraction resulting from the absolute undiscoverable movement of each system through space. The constancy of the observed velocity of light for each system, and the establishment of a consistent "timing" of events, common to all observers throughout a system, also depend upon this real contraction. Since all experimentally determined velocities, including that of light, result from some expression of the form $c' = l'/t'$, where l' is a fixed measured length and t' an observed interval of time, the value of c' will vary inversely with the value of t', but the product $c't'$ will have the fixed value l' independently of the rate of time movement. The same is true for $v't'$, and the ratio v'/c' will also be independent of the rate of time movement, provided that this latter is constant. In this way all expressions containing a problematic absolute value for c' and v' can be eliminated, and the concrete observed values $c't'$, $v't'$ can be substituted, *i.e.* velocities and times can be written down in the specialised form in which they must enter into any equation containing space co-ordinates. The form of the Lorentz transformations changes, but the mathematical contents remain identical.

PARIS.

Academy of Sciences, December 1.—Charles **Moureu**, Charles **Dufraisse**, and Marius **Badoche**: Auto-oxidation and antioxygen-action (XII.). Researches on the active auto-oxidisable form of acrolein.—Auguste **Bépal**: The fifth international conference of pure and applied chemistry, held at Copenhagen, June 16 to July 1, 1924.—Georges Claude was elected a member of the division of the applications of science to industry, in succession to the late H. de Chardonnet.—**Mordouhay-Boltovskoy**: The impossibility of an algebraical relation between π and e.—Bertrand **Gambier**: The polygons of Poncelet generalised.—Maurice **Gevrey**: The integration of the equation of dynamical tides.—E. **Huguenard**, A. **Magnan**, and A. **Planiol**: The measurement of the aerodynamical stresses supported by the wings of an aeroplane.—Jean **Boccardi**: Averaging by tenths of a year in variations of latitude. The usual method of taking the means of the values of the latitude, ϕ, by tenths of a year, has inconveniences and may lead to erroneous conclusions.—J. **Prédhumeau**: A new apparatus for the automatic construction of contoured maps by photographic restitution. An apparatus, named the "stereotopometer," is described, capable of giving maps with contour lines from photographs taken at the level of the ground. The method is purely optical, and this is claimed as better than the optico-mechanical methods previously described. The accuracy of the results is independent of distortion due to the photographic objectives.—Nicolas **Perrakis**: The thermodynamical interpretation of ionisation potential. The atom is transformed and equilibrium is maintained, due to the expulsion of an electron, the departure of which absorbs a quantity of entropy equal to C_1T, where C_1 is the thermo-electronic constant, $4{\cdot}07 \times 10^{-27}$ cal./deg.—A. **Dufour**: The distortion of an electromagnetic perturbation propagated along an insulated conducting line.—G. **Bruhat** and M. **Pauthenier**: The theory of electrostriction in insulating liquids.—Michel **Doloukhanoff**: The automatic regulation of the power of an electrical

installation. In an electrical installation composed of n machines of different powers, the number of combinations is $2^n - 1$, each working at or near its maximum capacity, and consequently with maximum efficiency Thus four dynamos of 100, 200, 400, 800 kilowatts will permit of the range 100 to 1500 kilowatts, in 100 kilowatt steps and with a favourable power factor The application of the same principle for other electrical machinery is outlined —— **Rateau** Remarks on the preceding communication The use of approximate geometric series —E **Carrière** and **Arnaud** Determination of the boiling-point curves and dew points of mixtures of hydrochloric acid and water under a pressure of 760 mm The experimental results are given in tabular and graphical form — J **Heyrovsky** Applications of the method of electrolysis with the mercury drop cathode —M N **Goswami** The direct hydrogenation and dehydrogenation of acenaphthene Sabatier and Senderens showed that their method of hydrogenation with nickel at 210°-250° C converted acenaphthene into tetrahydroacenaphthene, $C_{10}H_{10}\begin{matrix}CH_2\\|\\CH_2\end{matrix}$ If the temperature of the nickel is lower, 150° C, a mixture of tetrahydro- and decahydroacenaphthene is obtained, separable by fractional distillation If the vapours of acenaphthene, without hydrogen, are passed over nickel at 300° C, a good yield of acenaphthylene, $C_{10}H_8\begin{matrix}CH\\\|\\CH\end{matrix}$, is obtained — P **Lebeau** The presence of ethane in fire-damp from the Mines de Gagnières The presence of about 2 per cent of ethane together with traces of unsaturated hydrocarbons (0·04 per cent) in this fire-damp was proved The method followed was liquefaction at 215° C, with subsequent fractional distillation —Jacques de **Lapparent** The phenomena of sedimentation in the Cretaceous and Eocene strata in the Western Pyrences —I **Thoulet**. The liquid clouds of the ocean — Ph **Wehrle** and A **Viaut** The notion of interference in dynamic meteorology — L **Petitjean** The displacement of fronts of discontinuity —P **Martens** The cycle of the somatic chromosome in *Histera ovata* — K **Kvapil** and A. **Němec** The relation between the "absolute air capacity" and the degree of acidity of forest soils. The absolute air capacity, defined as the volume of the pores of the soil which, after saturating the soil with water, remain filled with air, is a physical property of fundamental importance as regards fertility The acidity, P_H, and the absolute air capacity have been measured for fifteen samples of forest soil, of which five were taken from forests containing conifers only, five from forests planted with deciduous trees only, and the remainder from regions planted with both —E **Rabaté** The action of dilute sulphuric acid upon fields of cereals Dilute sulphuric acid (4-10 per cent.), sprayed at a suitable stage of growth on growing cereals, has been proved to fertilise the soil, destroy weeds, check the action of certain parasites, and give an increased yield of 200 kgm to 300 kgm. of seed per hectare at a cost of less than 100 francs.—A **Policard** The phenomena of fluorescence determined in the tissues by Wood's light (radiations of wave-length 3650 Å) Application to the histology of the human ovary. Sections which appear uniformly white under ordinary daylight illumination, show differences of colour under the Wood light, indicating differences of constitution A detailed account is given of the application of this new histological method to the examination of the human ovary —P de **Beauchamp** The transmission of variation in rotifers of the genus Brachionus — Mlle France **Gueylard**. The influence of life in salt water on the development of the spleen in fishes In fishes capable of living in fresh and in salt water, a prolonged sojourn in the latter leads to a reduced development of the spleen —Léon **Blum**, Maurice **Delaville**, and Van **Caulaert** Modifications of the blood resulting from anaphylactic shock The method of ultrafiltration has been applied to the blood After anaphylactic shock, there is a marked increase in the proportion of calcium passing through the ultra-filter This effect is constant, and indicates a change in the protein colloid

CAPE TOWN

Royal Society of South Africa, October 15 — J S **Thomas** and W F **Barker** The partial pressures of water and sulphuric acid vapours over concentrated solutions of sulphuric acid at high temperatures (Preliminary note) The method adopted was the dynamical one of bubbling a carefully measured volume of air through acid at the required temperature and accurately determining the total quantity of vapour removed and also the amount of sulphuric acid contained in this vapour Only one concentration, 95 per cent, has been completely worked out Extrapolation of the total pressure curve to 760 mm gave the value 304° for the boiling-point of the acid, this compares favourably with the experimentally determined value 303°-307° —E **Newbery** On the application of the cathode ray oscillograph to the study of electrode phenomena (Preliminary note) The cathode ray oscillograph, supplemented with a thermionic valve, has been applied to the study of the single potential curves of a series of metallic cathodes in dilute sulphuric acid during make and break of the current through the cell Evidence of the existence of transfer resistance was obtained The direct method of measuring overvoltage cannot be relied upon in any circumstances, the commutator method gives true values only when extrapolation to infinite speed is carried out All the phenomena observed are readily explainable on the hydride theory of overvoltage —D F **Morrison** The pharmacological action of *Acokanthera spectabilis* The main action is on the heart, and is similar to that of digitalis The hour dose for frogs, and the minimal lethal doses for cats, rabbits, guinea-pigs, and rats show that the plant, which is indigenous to South Africa, possesses a high degree of toxicity There is a relative immunity on the part of the rabbit The plant contains glucosides. —M R. **Levyns** Note on some Peninsula plants. New or interesting plants from the Cape Peninsula

Diary of Societies.

SATURDAY, JANUARY 10

BRITISH ECOLOGICAL SOCIETY (Annual Meeting) (at University College), at 10 A M.—Prof F E Weiss Plant Structure and Environment (Presidential Address).—Prof Oliver Blakeney "Far Point".—Prof Fritsch The Algæ of Swiftly Flowing Streams.—Prof Yapp: Deposition of Frost on Leaves

INSTITUTE OF METALS (London Section) (at Institute of Marine Engineers), at 7.30.—Dr R H Greaves Extensometers

MONDAY, JANUARY 12.

ROYAL IRISH ACADEMY, at 4.15

ROYAL SOCIETY OF EDINBURGH, at 4.30.—E L Gill The Permian Fish Dorypterus.—E A Baker The Blackening of the Photographic Plate at Low Densities.—Dr E L Ince The Modes of Vibration of a Stretched Membrane with a particular Law of Density

INSTITUTE OF TRANSPORT (Yorkshire Local Section) (at Town Hall, Leeds), at 5.30.—J B Hamilton Inaugural Address

INSTITUTION OF ELECTRICAL ENGINEERS (Western Centre) (at Merchant Venturers' Technical College), at 6.—W B Woodhouse: Presidential Address

INSTITUTION OF AUTOMOBILE ENGINEERS (at Chamber of Commerce, Birmingham), at 7.—Dr S S Pickles The General Manufacture of Rubber (Lecture)

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—W Day and others Discussion on Telephonic Development in Great Britain and in the United States

INSTITUTION OF ELECTRICAL ENGINEERS (North-Eastern Centre) (at Armstrong College, Newcastle on Tyne), at 7.15.

INSTITUTE OF METALS (Scottish Section) (at 39 Elmbank Crescent, Glasgow), at 7.30.—Open Discussion

SURVEYORS' INSTITUTION at 8

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Major R W G Hingston Animal Life at High Altitudes.

INSTITUTE OF BREWING (at Engineers' Club).—J Stewart: The Season's Barleys

TUESDAY, JANUARY 13.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Prof. A Fowler: The Analysis of Spectra (1)

INSTITUTION OF MECHANICAL ENGINEERS (South Wales Branch) (at Swansea), at 6.—A A Fordham Steel Construction as applied to Steel Works and Mill Buildings

INSTITUTION OF CIVIL ENGINEERS, at 6.—Prof A H Gibson The Investigation of the Surge-Tank Problem by Model Experiments.—F Heywood The Flow of Water in Pipes and Channels.

INSTITUTION OF AUTOMOBILE ENGINEERS (at Royal Society of Arts), at 7.—Dr. S. S Pickles The General Manufacture of Rubber (Lecture)

INSTITUTION OF ELECTRICAL ENGINEERS (North Midland Centre) (at Hotel Metropole, Leeds), at 7.—W B. Woodhouse Presidential Address

MANCHESTER METALLURGICAL SOCIETY (at College of Technology, Manchester), at 7.—F C H Lantsberry. Tool Steels.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—A S Watson: Portraiture of Men

INSTITUTION OF AUTOMOBILE ENGINEERS (Coventry Graduates Meeting) (at Broadgate Café, Coventry), at 7.15.—A E. Barrett: Piston Rings.

SOCIETY OF CHEMICAL INDUSTRY (Birmingham Section) (at University), at 7.15.—H. L Heathcote: The Testing of Resistance to Tearing.—D. F Twiss and F Thomas A Comparative Study of some Vulcanisation Accelerators.

INSTITUTION OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND (at 39 Elmbank Crescent, Glasgow), at 7.30

INSTITUTE OF METALS (North East Coast Section) (at Armstrong College, Newcastle-on-Tyne), at 7.30.—A. R. Page: Blazing.

QUEKETT MICROSCOPICAL CLUB, at 7.30.—S. R. Wycherley: The Mounting of Chemicals for the Polariscope.

ROYAL SOCIETY OF MEDICINE (Psychiatry, Neurology, Disease in Children, and Epidemiology Sections), at 8.30.—Dr. P C P. Cloake and Dr F C. Shrubsall (Psychiatry), Prof. E. Bramwell (Neurology), Prof A Hall (Disease in Children), Dr. McNalty and Dr Parsons (Epidemiology), and others. Discussion on The Mental Sequelæ of Encephalitis Lethargica

INSTITUTION OF ELECTRICAL ENGINEERS (Scottish Section).

WEDNESDAY, JANUARY 14.

ROYAL SOCIETY OF ARTS, at 3.—Lt Col. G M Richardson: Dogs in Peace (Di Mann Juvenile Lectures)

ROYAL SOCIETY OF MEDICINE (Balneology and Climatology Section), at 5.30.—Dr. V Coates Clinical Types of so called Infective Arthritis

RADIO SOCIETY OF GREAT BRITAIN (Informal Meeting) (at Institution of Electrical Engineers), at 6.—S Ward Some Notes on Short Wave Reception

INSTITUTION OF CIVIL ENGINEERS (Informal Meeting), at 7.—H J Deane and others Discussion on The Use and Abuse of Reinforced Concrete

INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (at Birmingham University), at 7.—H W. Taylor Three Wire Direct-Current Distribution Networks Some Comparisons in Cost and Operation

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Graduate Section) (at Bolbec Hall, Newcastle-on Tyne), at 7.—J Calderwood Propeller Design

ENTOMOLOGICAL SOCIETY OF LONDON, at 8.—Annual Meeting

THURSDAY, JANUARY 15

ROYAL SOCIETY, at 4.30.—Sir Charles Sherrington and E G T Liddell Further Observations on Myotatic Reflexes.—Prof A V Hill, C N H Long and H. Lupton Muscular Exercise, Lactic Acid, and the Supply and Utilisation of Oxygen Parts I. II, and III.—Prof A P Chattock The Physics of Incubation.—H M Carleton Growth, Phagocytosis, and other Phenomena in Tissue Cultures of Fœtal and Adult Lung.—J. F Fulton (*a*) The Influence of Tension upon the Electrical Responses of Muscle to Repetitive Stimuli, (*b*) Some Observations upon the Electrical Responses and Shape of the Isometric Twitch of Skeletal Muscle, (*c*) The Relation between the Durations of the Isometric Twitch and of the After action of Tetanus.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—J S Huxley: The Courtship of Animals and its Biological Bearings (1)

INSTITUTION OF MINING AND METALLURGY (at Geological Society of London), at 5.30.

INSTITUTION OF AUTOMOBILE ENGINEERS (London Graduates Meeting) (at Watergate House, Adelphi), at 7.30.—A E L Colline: Steam Vehicles for Road Transport

OPTICAL SOCIETY (at Imperial College of Science and Technology), at 7.30.—A Steavenson A Peep into Sir William Herschel's Workshop

CHEMICAL SOCIETY, at 8.—E. E. Turner and A B Sheppard. 6-Chlorophenoxarsine.—G A R. Kon and R P. Linstead The Chemistry of the Three Carbon System. Part III. $\alpha\beta$-$\beta\gamma$ Change in Unsaturated Acids, Part IV A Case of Retarded Mobility

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at 11 Chandos Street, W.), at 8.15.—Lt.-Col A T Gage and Lt Col. Clayton Lane: The Alkaloids of Cinchona and Malaria

INSTITUTION OF RUBBER INDUSTRY (at 16 St Mary's Parsonage, Manchester).—J. Adamson: History of the Rubber Industry in Manchester

FRIDAY, JANUARY 16.

ROYAL SANITARY INSTITUTE (at Town Hall, Newcastle on-Tyne), at 4.—Dr A F. G Spinks, H. H. Evers, and others Discussion on Maternity and Child Welfare Practice

ROYAL DUBLIN SOCIETY, at 4.30

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group), at 7

INSTITUTE OF METALS (Swansea Section) (at Swansea University College), at 7.15.—Prof C A Edwards. Alloys and their Properties

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—Major A M. Taylor. The Hexaphase System and the Compensated 3 Phase System for 150,000 Volts Transmission with Records of Test.

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (at Technical College, Cathays Park, Cardiff), at 7.30.—T. Lewis: Chemical Constituents of Ductless Glands.

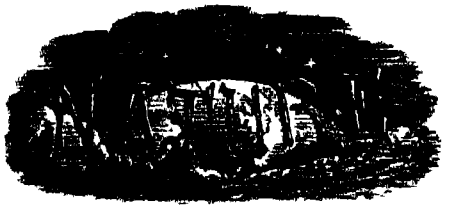
SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Group jointly with the London Section) (at Royal Society of Arts), at 8.—T. W. Stainer Hutchins, Dr. C H. Lander, and others Discussion on The Low Temperature Treatment of Bituminous Materials

SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section) (at Liverpool University), at 8.—Sir Max Muspratt, Bart. Chemistry and Civilisation (Hurter Memorial Lecture).

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Sir William Bragg: The Investigation of the Properties of Thin Films by means of X-Rays.

PUBLIC LECTURES.

WEDNESDAY, JANUARY 14



LONDON SCHOOL OF ECONOMICS AND POLITICAL SCIENCE, at 5.—B. J. Fletcher. The Principles of Design (Introductory Lecture).

ST. BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE (Physiology Department, 6 Giltspur Street, E.C.1), at 5.—Prof. C. Lovatt Evans: The Physiology of Plain Muscle. (Succeeding Lectures on January 21, 28, February 4.)

KING'S COLLEGE, at 5.30.—Prof. A P. Newton: The World of the Middle Age.

THURSDAY, JANUARY 15.

UNIVERSITY COLLEGE, at 2.30.—Miss Margaret A. Murray. Egyptian History (Introductory Lecture).

SATURDAY, JANUARY 17, 1925.

Research in Agriculture.

ALTHOUGH the Development Commissioners are not themselves directly responsible for agricultural education and research during the last fourteen years, the manner in which the funds subject to the jurisdiction of the Commissioners have been portioned out has exercised a dominating influence on both the quality and quantity of scientific information that has been recently acquired, and on the nature of the organisation by which it has been sought to render this information of immediate assistance to the farmer. If the fourteenth Report of the Development Commissioners (H.M.S.O., 4*s* net) is read in conjunction with the first and later reports, it will be noted that the Commissioners have favoured and adhered to a more or less definite policy from the outset. They realised that one of the primary needs was to assist in the training of men competent to conduct research, and then to accelerate research on the fundamental problems underlying agricultural practice. The body of scientific men at present employed in connexion with agricultural science is to-day vastly greater than it was fourteen years ago, and it is probably not too much to say that the average training which these men have received, and also the attainments and qualifications of the average man, are decidedly better.

It has been the policy of the Commissioners to add to the volume of research, chiefly by assisting in the initiation and maintenance of Research Institutes and Experimental Stations, and there are now about twenty such stations in Great Britain dealing with fundamental problems. It is interesting in passing to note that the necessity of having more than one institution to deal with certain problems which have specially local application has now been realised and acted upon, thus England, Scotland, and Wales has each a Plant Breeding Station aided by grants from the Development Fund, while the needs of horticulture, for example, are recognised at more than one institution.

The Report before us affords ample evidence of the quality and quantity of the research in progress at these institutions. It is beyond the scope of the present article to attempt to review this work. It is necessary, however, to lay emphasis on its fundamental character, the vast majority of the scientific papers for which the staffs of the institutions have been responsible dealing with difficult problems approached in an exhaustive manner and by purely scientific methods. There can, in short, be not the least doubt that the policy of the Development Commissioners has been successful to a marked degree in two highly important directions. To-day we have, comparatively speaking, a large, and in the main a well-qualified, body of agricultural scientific workers, and a vast mass of accurate scientific

data of great potential value to the farmer and to the nation. No reasonable criticism can be levelled against the Commissioners for the manner in which the funds have been apportioned in relation to solving the problems of the various branches of the industry, although to some it may appear that horticulture has been treated more generously than would at first sight seem to be justified by its position in Great Britain. It has, however, to be realised that horticulture is an intensive industry employing a considerable amount of labour, and thus any extension of fruit culture or market gardening must immediately and inevitably react in a favourable manner on the rural population.

It is obvious that science cannot of itself redeem an industry which is in the main under-capitalised and very largely unprofitable It should, however, be equally obvious that if the conference of land-owners, farmers, and land-workers recently convened by the present Government can in fact agree on a sound agricultural policy at once far-sighted and acceptable to the nation as a whole, the ultimate success of that policy will be largely determined by the extent to which science is brought to the direct aid of the farmer. It is, therefore, legitimate to examine the organisation which exists to-day for the explicit purpose of bringing science to the direct aid of the farmer, and to do so in the light of what are considered to be the chief necessities of British agriculture, if this industry is to be regarded as of national importance as well merely as of something which concerns the well-being of what is no inconsiderable proportion of our population.

The Commissioners have, of course, realised the necessity of a connecting link between the Research Institutions and the county organisers who are primarily responsible for advising the farmer as to scientific practices. Advisory officers are now attached to fourteen institutions; the majority of these are, however, advisory chemists and pathologists whose chief preoccupation in most cases is to undertake research on laboratory lines into problems of local importance, and in the main they have not the facilities to investigate farm practices as such. It is therefore satisfactory to note that Advisors in Economics are now being appointed at some of the institutions, and the work already done, notably at the University of Leeds, would seem to indicate that, particularly when the officers devote their attention to the economics of local practices, they are able to afford signal service to the farmers within their areas. Recent results obtained at the Research Institutes in the realm of animal nutrition have been followed up at college farms by accurate feeding trials, so that it is now possible for organisers who have had the opportunity of gaining personal experience to give authoritative advice to individual farmers, which has in innumerable cases revolutionised the system of feeding adopted. In this connexion the pioneer work of Mr. Boutflour in Wiltshire affords one of the best recent examples of the way in which science has been brought to the direct and very substantial aid of the farmer, and has incidentally caused increased production, in this case in terms of gallons of milk. It is perhaps open to doubt, however, whether science has been brought sufficiently to bear on some of the wider and more national aspects of agriculture in Great Britain.

Mr. Edward Wood, the Minister of Agriculture, in recent speeches and referring to the conference of those concerned in the industry he has convened, has emphasised the need of adding to the area under cultivation in Great Britain, not necessarily by merely thinking in terms of wheat alone, and he has directed attention to the paramount need of making our more derelict lands fertile and this whether particular areas are left in grass or brought under the plough. Mr. Wood has also directed attention to the serious disadvantage under which the farmer labours in regard to bringing his farm into a higher state of fertility as the result of paucity of readily available working capital.

Broadly stated, then, one of the first necessities, if we are to have a healthy agriculture, is a campaign of land improvement in the widest sense, and from the facts of the case, no matter whether credit facilities are to be afforded to the farmer on a large scale or not, the improvements must be effected on an economic basis.

Here, then, is a concrete, yet highly composite problem, a problem towards the solution of which agricultural science has admittedly accumulated a vast array of data But the items contributing to such data are largely unrelated and cannot at present be said to constitute a definite and trustworthy practical doctrine.

The allied questions of improving poor land and generally enhancing the fertility of farm lands in Great Britain as a whole are not subjects upon which the organiser can easily persuade the farmer himself to experiment. The problems involved entail, first, difficult economic considerations, and secondly, the elucidation of practical difficulties connected with the type of rotation and systems of cropping most suitable, methods of tillage, processes of manuring, relation of grass to arable, and the choice of the correct varieties and strains of crops. The general problem is not, moreover, one that is likely to be adequately dealt with at an institutional farm; for one thing, these farms are frequently of a higher grade than the average of the district which they represent, and for another, it is usually the policy to run such farms in conformity with the generally accepted canons of good husbandry.

Indirectly, valuable work has been accomplished in

the direction of surveying the field by the various soil and other surveys that have been undertaken. Hitherto, however, no large sum of money has been set aside for this important work, which has been conducted in a somewhat haphazard manner and in many cases without critical regard to economic considerations. In any event, it is work that needs to be conducted on a well-thought-out and uniform plan, under the general supervision of a strong co-ordinating authority. The need of a complete agricultural survey showing both actualities and potentialities was rendered abundantly manifest during the War, while if a real endeavour is to be made to stabilise the industry and add to the productive capacity of farm lands in Great Britain, the non-existence of such a record will again be acutely felt.

In so far as growing the correct varieties of the chief crops is concerned, it is satisfactory to learn that a grant has been made to the National Institute of Agricultural Botany to enable that organisation to conduct subsidiary trials at carefully selected sub-stations. It is, however, on the poorer and more improvable types of land that variety trials are most needed, while in many cases the type of varieties necessarily handled by the National Institute are not likely to be those best suited to land of the lower productive classes. Trials of a somewhat different nature should also be initiated; the aim in the first place would be to discover the degree of productivity of every characteristic district, by setting up a series of properly replicated plots of the same standard variety—of a crop of wide-spread distribution such as oats—on as many farms as possible.

This is a procedure that should constitute an important feature of any general scheme of agricultural survey that may be set on foot, for without some really trustworthy quantitative and easily comparable crop data of this sort it is difficult to see how the results of surveys based on soil and other environmental factors can be interpreted to proper economic advantage. In the second place, it is exceedingly important to know the range of applicability of new and improved varieties, and it is just as important that the greatest possible number of farmers should be given the opportunity of forming their own opinion of such varieties.

With a view to these ends quantitative data are not necessary, or at all events not necessary in the first instance. A strip of, say, Yeoman wheat should be sown on a few fields in every parish in the country in which wheat, in no matter how small quantity, is grown. The same would apply to, say, Black Bell III. and Victory or Crown oats, while in particular districts it would be easy for the appropriate advisory centres to make proper suggestions as to varieties demanding extensive trials by this means. A similar simple method would make it possible rapidly and accurately to define the areas capable of successful lucerne cultivation, to establish the relative merits of widely different strains of such a fundamentally important crop as red clover for widely different habitats. All of these are problems of first-rate importance in relation to profitable land improvement.

More urgent than trials of the character indicated above is the necessity for conducting experiments in the realm of systems of cropping, and the relation of temporary to permanent grass, which would entail equally far-flung but more elaborate and long-continued field trials.

It is true that financial support has been given to further the idea of arable dairy-farming, and that the utilisation of barren sandy land has been under tentative investigation, but these are isolated aspects of the broad question of enhanced crop production and land improvement. They are not so much the province of agricultural chemistry or of agricultural botany as understood in Great Britain, but rather of field husbandry or agronomy as understood and investigated in the United States of America, for example

Notwithstanding the work that is in progress in many important directions influencing land improvement, it is probably not too much to say that the problems of field husbandry will not be solved until an *ad hoc* organisation is set up to deal with the matter in a manner analogous to that in which the Research Institutions deal with the fundamental problems of plant breeding and animal nutrition, for example, or the way in which the advisers in agricultural chemistry deal with their local problems It is doubtful, however, if a single Research Institute of field husbandry would adequately meet the case—numerous sub-stations would certainly be a necessity. It is, however, the principle that field husbandry is not at present a matter of demonstration, but is essentially a matter demanding field investigation of a most rigorous and accurate character, conducted without bias and in a true spirit of research, that must be realised Two things are essential, namely, a co-ordinating authority and the appointment of men in the counties backed with facilities for conducting field investigations on carefully selected areas. A useful beginning could undoubtedly be made if advisers in field husbandry were appointed at institutions serving backward and infertile districts, while co-ordination could be assured by the appointment of an officer at the Ministry of Agriculture charged with the supervision of the work as a whole. It is probable that in some cases suitable land could be taken over for experimental purposes from the not inconsiderable areas now under the control of the Forestry Commission, while it is more than likely that land-owners and farmers would be found in very appreciable numbers who would be willing to assist in such an important undertaking.

Human Geography.

Human Geography. an Attempt at a Positive Classification—Principles and Examples By Jean Brunhes. Translated by Prof. I. C Le Compte. Edited by Isaiah Bowman and Prof Richard Elwood Dodge. Pp. xvi+648 (London, Calcutta and Sydney: G. G. Harrap and Co., Ltd., n d.) 21*s.* net

THE student of modern geography by whom this classical work is read for the first time, might well feel that even in the few years, little more than a decade, since the original issue, most of this manual has become, if not out-of-date, at least somewhat antiquated A youthful applicant for a situation was asked "Where is Tokyo?" He replied, "I do not know." The employer expressed his astonishment in vigorous terms, and the youth continued, "But if you will tell me where it is, I will tell you why it is there." This youth was a product of his period, the geography of to-day seeks to answer the question "why?" The aim of modern geography is to probe, to evolve generalisations, to eliminate and thus simplify complex phenomena in which the psychological factor is of supreme importance.

M. Brunhes provides a useful corrective He writes and argues about what he has seen; he aims at a manual, not a treatise, at a collection of observed facts, not an explanation. Again and again he advises caution. The fundamental fact is place-relation, and he shows repeatedly how every thinker whose subject-matter implies some form of human activity needs the geographic sense. The Ricardian law of diminishing returns does not apply where the land, as such, is not the fundamental basis of property. Again and again the reader is referred to six essential facts: houses and roads, cultivated fields and domestic animals, exploitation of minerals and devastation in plant and animal life —facts familiar enough under a slightly different grouping of ideas in the terms shelter, food, and communications

By numerous illustrations and digressions the reader is led to an idea of geographic method, to a manner of attack upon a seemingly heterogeneous collection of an apparently endless mass of isolated facts, and the whole outlook may be summarised under the query "how?" not "why?" A heavy snowfall is to be expected in January in New York and other places where the mean January temperature is about, or below, freezing point. The "why" of this fact belongs to the domain of physical science: the recognition of the fact as a possible factor in regard to man's life on the earth belongs to physical geography. So far everything is simple, but the human geographer asks the question how is man affected? It is his business to find out how man reacts to this circumstance, and he finds widely different answers for different parts of the world. The response in New York is different from the response in Italy, and so he arrives at the fundamental concept of location, the tyranny not of Nature as a whole but of place-relationship within Nature.

M. Brunhes is deliberately didactic; he teaches by selected samples and begins with the simplest examples. The easiest studies refer to islands—not only the real islands of the sea, but also the land islands where a community is relatively isolated by physical circumstance; his study of the Balearic Isles leads to thoughts about Java or Japan. Herein, it would appear, lie the elements of age which might repel the modern student, for there is little consideration of the world as a whole; there is no room for the current broad generalisations which underlie the idea of the "major natural regions of the world." A regional synthesis, however, is not lacking. A map of Spain, for example, shows within the area of dry Iberia five regions of steppes and irrigation, and so illustrates a regional classification based, not upon the facts of climate, but upon the ways in which man has responded to one particular element, water supply.

In the last chapter it is argued that space, distance and difference of level are fundamental geographical facts which are becoming more and more the sovereign masters of men, and the final conclusion is reached that "Every people . . . covers the surface of the earth with those outward and visible signs . . . which allow us to divine its past and sometimes even its future." Whither does all this lead? Apparently to the notion that geography is not a science, not an ordered body of knowledge, which is independent of the personality of the investigator, not a set of conclusions which must be universally valid, not a statement of generalisations valid for all time or for every place, but primarily and fundamentally a discipline, an outlook on man's life on the earth, which gives to the thinker that unique geographic sense so invaluable for the law-maker, the captain of industry, and the merchant prince, so useful a corrective in all matters which pertain to the conduct of human affairs on the large scale.

Whatever view may be taken, it must be confessed that the facts of geography are stubborn; they cannot be melted in the mental furnace and run into set moulds; they frequently misfit the theories; but the spirit of geography is of unique value. No other human study permeates so many of the sciences; no other study is so necessary to the equipment of the educated man.

Optical Measuring Instruments.

Optical Measuring Instruments, their Construction, Theory, and Use By Dr. L C Martin (Applied Physics Series) Pp. ix+270+8 plates (London, Glasgow, and Bombay: Blackie and Son, Ltd, 1924) 17s 6d. net.

"OBTAIN a measurement, however rough; then endeavour to get a better," was the advice that Lord Kelvin used to urge upon his students Quantitative analysis is the natural supplement of qualitative reasoning One rough estimation may serve to exclude a multitude of suppositions, one precise measurement may serve to indicate the definite conclusion of an investigation. But to make a measurement, even an approximate one, is not always easy Precise metrology is a difficult art It demands an understanding of the problem, access to the requisite apparatus or, failing instrumental means, the capacity to design and, if necessary, construct whatever appliances may be required; skill in their adjustment and use; and, above all, the will to discard the obvious, which in metrology is not always the truth

As there is no superfluity of literature devoted to this particular subject, any new contribution, such as Dr. Martin's work on "Optical Measuring Instruments," will surely be welcomed As the author has stated in his preface, "The selection of instruments for description is extremely difficult" It is unlikely, indeed, that from the great mass of material that is nowadays available the same selection would be made by many. With the exception of Chap vii. devoted to rangefinders, it would appear that instruments of warfare have intentionally been rigorously excluded All the appliances cited have an essentially peaceful character. They comprise measuring microscopes, micrometers, comparators, the divided circle, theodolites and sextants, levels, spectrometers, refractometers, spherometers, focometers, photometers, and saccharimeters. In the final chapter, "Errors and Accuracies of Observation" are discussed rather more briefly than the importance of this question would warrant.

There is a similar brevity in the presentation of the general principles forming the subject of the first chapter, where the author in his discussion of the principles of geometrical supports is to be congratulated upon his emphasis on the importance of the physical conditions. These first and last chapters might well have been extended at the expense, if necessary, of other sections. For example, although the divided circle is a highly interesting precision tool, it is scarcely an optical instrument when stripped of its reading microscopes, which are dealt with in the preceding chapters. Rangefinders, which are essentially militaristic in character and of correspondingly limited interest, might also have been excluded, if thereby space could have been provided for a chapter upon that premier optical instrument of supreme accuracy—the interferometer, which has been brought in Great Britain to so high a standard of perfection. The chapter on the rangefinder, and particularly the stereoscopic portion, is the least satisfactory section of the book Evidently the author is unaware that the German claim which he emphasises on p 121 has been disproved beyond doubt as the result of extensive trials made by most of the principal powers interested in this subject, and that many important gunnery officers of the German Navy no longer accept it

Dr Martin's book has the merit of originality It is not a compilation from other works Originality in a first edition demands, however, particular care in the avoidance of errors, and unfortunately there are throughout this book mistakes of so obvious a kind that it is difficult to understand why they should have escaped correction. In Fig 45, which illustrates the application of an inverting prism to a sextant, the rays are quite incorrectly traced, as they are not shown touching the reflecting surface which determines the inversion of the image All three diagrams of Fig 93 are also incorrect. A ray normal to the surface of the prism (*a*) is shown refracted. In the next diagram, representing the same prism, the ray entering as before at scraping incidence is now shown refracted away from the base, the refracted ray within the dense flint prism being shown in an impossible position. According to Fig. 93 (*c*), a beam of light passing through an equivalent plane parallel plate is wrongly represented as suffering severe refraction instead of emerging parallel to its original direction

The mistakes are not confined to the illustrations: they occur also in the text As an example, the "special problem in angular measurement" at the end of the chapter on theodolites and sextants may be cited. The problem indicated is to measure the inclination of two lines It is proposed, instead of suitably rotating the cross-wire of a telescope with reference to the lines and a scale, to make use of a rotatable inverting prism As the author states, if such a prism is rotated about the direction of view, the inverted image rotates at twice the angular speed of the prism, and the conclusion is arrived at that greater accuracy of measurement is attained by these means. But, as the problem is the measurement of a particular angle, the prism will require to be rotated through only half the angle to be measured, and the comparative accuracy will accordingly be halved.

Although the majority of the mistakes are obvious ones, they may prove confusing to a thoughtful student, and more careful revision, particularly of the illustrations, is desirable in any future edition of the work.

JAMES WEIR FRENCH.

Sands and their Uses.

Sands and Crushed Rocks By Alfred B Searle. (Oxford Technical Publications) Vol. 1. *Their Nature, Properties and Treatment.* Pp xiv + 475 Vol. 2 *Their Uses in Industry.* Pp ix + 281. (London Henry Frowde and Hodder and Stoughton, 1923) 52*s* 6*d.* net.

MR. SEARLE has made an attempt to fill a gap in technical literature by a work which deals, in all aspects, with the subject of sands and crushed rocks According to the author, the purpose of the work is "to summarise in a convenient form such geological, chemical and mineralogical information on sands as is likely to prove of value to those engaged in the digging, sale, and many uses of these materials." To the reviewers, however, it seems that the author's enthusiasm for detail, much of which appears irrelevant, has defeated this purpose

A glance at the table of contents will reveal the varied nature of the material gathered together in Volume 1 Commencing with the origin and formation of sands, we finish with a chapter on their storage, packing and despatch In Chap. iii, ninety pages are devoted to a catalogue, arranged in alphabetical order with descriptive detail, in which names are given to nearly one hundred and fifty sands! For no obvious reason, a description of a carborundum furnace is here included Incidentally, there seem to be but few substances which, according to the author, do not come within the purview of this subject. For example, ground glass and metal filings are stated to have been used as "sands" in concrete, while "breeze" is described as an artificial sand consisting of sifted ashes The writer has departed considerably from the customary definition of a sand as a natural, detrital and non-plastic deposit. Chap iv, written on similar lines, deals with some of the mineralogical constituents of sands, while in the next two chapters their properties, as well as their examination and testing, are described

The remainder of this volume is concerned with the treatment which sands and sand rocks undergo before use It is profusely illustrated, but many of the photographs are reminiscent of the advertisement catalogue.

The second volume of the work enlarges upon the uses of sands and crushed rocks in industry. The uses of these materials in brick-making, in road construction, as refractory materials, in agriculture, in glass-making and in metallurgy, to mention only a few of the more important applications, all receive attention.

Many statements to which exception may be taken seem to have escaped the author's notice. For example, Stokes's law is first written as $V = \frac{2D - d}{9^2}$ and then quoted correctly on the next line. Referring to the constant weight obtained when a material has been fully dried we find the statement that "this weight, less that of the bottle and contents previous to drying, is the amount of moisture in the weight of materials used." In connexion with electrostatic separators, we are told that "a still more definite separation will take place if the whole of the material is first charged negatively and is then brought into contact with a positively charged body," while it is also stated that the "mean coefficient of expansion of silica between 0° C and 1000° C. is 0 68" Again, the figure on p 437 (I) given in illustration of a "gas-fired" furnace does not represent a gas-fired furnace Finally, we are told that "a tunnel-kiln efficiently insulated with kieselguhr on the sides and roof can usefully employ 98 per cent. of the available heat in the fuel."

Elsewhere, there becomes apparent a certain looseness of style, and this gives rise to statements which may be ambiguous or often misleading. For example, the refraction of light is described as the *turning* of a ray of light, while on p. 208, Vol. 1, it is explained that doubly refracting materials "turn a ray of white light through several different angles, so that the rays are termed ordinary and extraordinary rays."

Moreover, the book contains inconsistencies, one example of which cannot be allowed to pass unnoticed. "Tridymite bricks are silica bricks in which the whole of the silica has been converted into tridymite. . . . No brick on the market consists entirely of the low specific gravity forms of silica"

The breadth of field which the subject covers, the inaccessibility of many publications, and considerations of space, are put forward in the preface as a plea for the omission of full references. But surely the time has come when few technical or scientific works, other than the most elementary, can stand the test of publication without the support which adequate references to the literature of a subject gives. The necessary space could have been gained by the elimination of much of the unnecessary matter and by avoiding repetition.

A judicious selection of the references the author must have accumulated during the many years in which, as he tells us, he has read the leading journals

on the subject, would undoubtedly have enhanced the value of this book and been of permanent worth

The volumes are well printed and well presented, but the price is high, and the author would have done well to have compressed his subject-matter into a smaller space. Doubtless much useful information will be found, especially in the second part, by those for whom the author has written, but the gap in the literature still remains L S. T

An Oxford Sketch of the Evolution of Thought.

Speculum Mentis, or the Map of Knowledge By R. G Collingwood Pp 327 (Oxford · at the Clarendon Press, 1924) 12s 6d. net.

MR COLLINGWOOD has a tradition of art behind him and he has also made himself recently one of our leading authorities, if not the first of all, on Roman Britain As he adds to this a profoundly philosophic mind, his attempt in this book to survey the whole field of human thought has some material for its foundation It is modest in expression though ambitious in scope, and will interest greatly those who like to trace a line of thought faithfully pursued by a thinker who wrestles hard with every conclusion, and gives the public nothing but what he has won from his own experience, intensely felt

The general thesis of the book is that the human mind, whether in the individual or in the race, passes through a series of experiences each of which is incomplete and partially corrected by the succeeding stage, until it rests at last in a philosophy of absolute or final worth based on the mind itself, enlightened by history It will be seen that there is a large heritage from Hegel here, and if one wished to describe the point of view in terms of older thinkers who have influenced the writer, one would say that it was Hegelianism plus Croce But this would do scant justice to Mr Collingwood's sincerity of thought and striking individuality. One appreciates the book most as a personal revelation.

Art is the first, and always the primitive, stage of thought; and this passes into the kindred, concrete and unanalysed stage of religion Analysis, when it comes, gives us science, which appears in Mr Collingwood's hierarchy of thought as the middle term. Art and religion are below or before it · history and philosophy above or after. We are not to imagine that the lower stages are entirely superseded by the higher; they are rather corrected and subsumed in a fuller point of view.

The use that Mr. Collingwood makes of the recent historical spirit in science is very apt and enlightening. It is the clearest and most conclusive part of the whole book. During the nineteenth century many of the sciences, as he tells us, restated their problems in terms of history Astronomy realised that its proper task was to explore the history of the stellar universe; geology and geography united to study the history of the earth, and biology came to see that the problem of species is the problem of the origin of species "The time seems near at hand when science will feel the need of absorbing itself bodily in history and re-shaping its problems throughout in historical terms."

This passage from science to history is one of the numerous points in the book where a penetrating light is thrown by the author's synthetic and persevering thought He might perhaps have made his effect better by a little more compression There is a good deal of repetition, and the reader himself needs perseverance, but he will be richly rewarded It is one of the most profound and suggestive treatises of recent years F. S MARVIN.

Our Bookshelf.

The Design and Working of Ammonia Stills. By P Parrish Pp 300 (London. Ernest Benn, Ltd., 1924) 40s net.

THREE hundred thousand tons of ammonium sulphate are produced annually in Great Britain by the direct distillation of the ammoniacal liquors arising from coal and shale products Even from this consideration alone, the publication of the first standard comprehensive book in English on the design and working of ammonium stills must be regarded as an event not only of scientific but also of economic importance. Many chemical manufacturers in the past for various reasons have endeavoured to keep their processes strictly secret, and improvements have come from internal experience on the plant rather than from general physico-chemical considerations or from a combined study of the theoretical and applied aspects of the problem or difficulty encountered "Collaboration," Dr Charles Carpenter notes in the preface, "between those responsible for the design of large-scale chemical plant can only be a war-time measure" Mr. Parrish will help to some extent to remove in one industry this individual outlook and veil of secrecy, for in his book he has collected together a great amount of novel information of a fundamental and authentic character on the subject of ammonia stills and accessory plant This carefully-edited book, which includes 170 excellent illustrations and 70 technical tables, must benefit the industry generally and secure a common outlook for new developments on other than empirical lines

It is indicated that the greatest economy in the manufacture of ammonium sulphate is likely to accrue from a better utilisation of the available heat of the process, and the aim of the author has been to show how this can be achieved. In fact, so keenly has the point been emphasised that the volume might be

called the design of ammonia stills in relation to steam economy and the utilisation of potential heat The fundamental principles underlying the design of stills, preheaters, condensers, dephlegmators and coolers all receive thorough consideration in this connexion The opinions put forward are those of a successful works' chemist who writes more particularly for the benefit of other gas chemists and engineers rather than for the guidance of the chemical student

A note of criticism might be made on the general use of chemical formulæ in a somewhat loose manner, while the chemical equations given are not always correct.

In conclusion, it should be stated that the financial aspect of the subject of ammonia distillation also receives detailed treatment, and the author makes every effort to indicate the economic soundness of processes under particular conditions

JOS. REILLY

The Subject Index to Periodicals, 1921 Issued by the Library Association. *B-E · Historical, Political and Economic Sciences.* Pp 106. 21*s* net *F Education and Child Welfare* Pp. 28. 4*s* net. (London: Grafton and Co , 1924)

WE welcome these two sections of the Subject Index to Periodicals published by the Library Association. They maintain the high standard attained in previous sections of this catalogue. These sections index papers published in 1921, so that the Association is now allowing a little less time to elapse between the date of publication of the original papers and that on which the Subject Index is issued. It would, of course, be more useful to those engaged in scientific work if it were found possible to shorten the interval to somewhat less than three years, and the Library Association will, no doubt, when it has overcome all the difficulties connected with a work of this kind, find it possible to issue its Indexes within a period of two years from the date of publication of the periodicals indexed

Among those subjects in the section on historical, political and economic science to which particular attention has been paid we notice agriculture, banks and banking, bolshevism, chemical manufacturers, coal trade, co-operation, the Eastern question, employees and employment, ethnology, the European War, fisheries, forestry, international law, labour, mines, railways, shipping and wages.

The section on education and child welfare will be of great value to those who are devoting themselves to the study of these subjects. An examination of the 54 columns of titles of papers in this section will show the direction in which the thoughts of those advocating reforms have been chiefly turned. We note especially educational psychology and mental tests, and papers on the position of teachers. Papers on the teaching of citizenship are grouped together, as are also those on abnormal and backward children. The question of classical education has, of course, a heading to itself. Papers coming under the general head of education occupy nine columns of the Index, but these are subdivided under various subheadings which make reference easy. There are also headings for science study and for technical education.

Thysanoures, Dermaptères et Orthoptères de France et de la faune européenne. Par Prof. C. Houlbert. (Encyclopédie scientifique: Bibliothèque de Zoologie.) Tome I Pp. xii + 382. (Paris: Gaston Doin, 1924.) 16 francs.

THIS clearly written and well-arranged little volume forms a handy and up-to-date work of reference to the orders of insects concerned. The longest section (Part I.) is devoted to the Apterygota or, as Prof. Houlbert prefers to term them, the Thysanura. These he divides into the two sub-orders Collembola and Monomorpha (Thysanura of most authorities) It is prefaced by a general account of their structure (based largely upon the work of Willem), and there follows an exceedingly useful series of family and generic keys, along with descriptions of the various species This section of the volume should appeal to many entomologists since it provides a readily accessible guide to the insects of those two orders The work of Lubbock has long been out-of-date, and the student has hitherto had to rely upon various scattered memoirs (some not easily procurable) for the identification of his material. Part II. deals in a similar manner with the Dermaptera, and Part III is devoted to the general structure and habits of the Orthoptera, descriptions of the species of the latter order being reserved for a second volume The book is fully illustrated and has ample bibliographical references A D I

A Comprehensive Treatise on Inorganic and Theoretical Chemistry By Dr. J. W. Mellor. Vol. 5: *B, Al, Ga, In, Tl, Sc, Ce, and Rare Earth Metals, C*, (Part 1). Pp. x + 1004. (London: Longmans, Green and Co , 1924.) 63*s* net

THE new volume of Dr. Mellor's Treatise includes boron, aluminium, and the rare earth metals, together with a considerable part of the section on carbon. The style and general method of treatment are similar to those used in the earlier volumes and do not call for any comment. Perhaps the most striking feature of this volume is the treatment of the complex compounds of boric acid. Some of these can only be expressed by formulæ such as $KMg_2B_{11}O_{19}$, $9H_2O$, $Mg_7B_{16}O_{30}Cl_2$, or $Cd_5\{H_4[B(W_2O_7)_6]\}_2$, $51H_2O$, and would certainly be omitted from any elementary text-book, but they all find a place in the comprehensive treatise of the author, just as readily as if their compositions could be expressed by formulæ of the simplest kind

The "Chemical Age" Chemical Dictionary: Chemical Terms. Pp. 158. (London · Ernest Benn, Ltd., 1924.) 16*s*. net.

THE dictionary gives the definitions and in many cases short descriptions of a large number of terms used in chemistry. Practically all branches are covered, and the book is up-to-date. A few sections, taken at random, were: deanimation, hæmacytometer, isomerism, oligodynamic action, quinocarbonium, thermodynamics, ultramicroscope, and X-ray analysis, and in each case a clear and accurate account of the topic was presented. The book should prove useful to technical journalists and for general reference, as well as to chemists

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Resonance Radiation and the Correspondence Principle.

THE experiments of Wood and Ellett[1] on the polarisation of the resonant radiation of mercury suggest that it is necessary to make a rather important modification in the quantum theory. The theory of the phenomenon has been examined by several writers,[2] among whom Eldridge has most explicitly directed attention to a case of difficulty. He shows that the observations in a magnetic field are a natural consequence of regarding magnetism as equivalent to rotation, provided that the effect without field is given, but that this effect without field conforms rather to the classical than to the quantum theory.

This is the difficulty. Suppose light of wave-length 2537 Å.U. going northwards and polarised with electric vector in a vertical plane—the points of the compass are merely used to describe relative directions. If this light falls on mercury vapour, an observer to the east sees the resonant light almost completely polarised in a vertical plane, and one above sees practically no light at all. The wave is that which, on the classical theory, would be emitted by an electron vibrating in a vertical line; it may conveniently be called a *linear* wave, and similarly the wave emitted by an electron revolving in a circle may be called a *circular* wave. According to the quantum theory, the resonant line of mercury is associated with a change of angular momentum, and so each atom should emit a circular wave. There is little known in the quantum theory about the process of excitation, but as the electric force is vertical it is natural to suppose that it would give the atom angular momentum about some horizontal axis. However that may be, the radiations from the separate atoms are not coherent, and no possible combination of incoherent circular waves can give rise to a linear wave.

Some sort of explanation could perhaps be constructed by supposing that the electric force in the incident light itself orientated the atoms, and that the resonant radiation was controlled by a Stark effect. This does not really remove the difficulty, for if the vapour were illuminated by circularly polarised light the atoms would have continually to re-orientate themselves, and at such a rate that the concept of the angular momentum of the atom would lose all meaning. The plain fact is that we are dealing with a "degenerate" system, and the degeneracy is of a new kind, exhibiting itself externally and not merely as a purely conceptual question. Any explanation has to face the fact that the atoms are orientated arbitrarily. Since they react to the light in a manner independent of this arbitrary orientation, we must suppose that each single atom is somehow much more isotropic than would be admitted by the ordinary Bohr model. This isotropy might perhaps be attained by supposing the process of excitation to be so slow that the atom passes through all phases of its motion before it is complete.

[1] Wood and Ellett, Proc. Roy. Soc. A, cili. p. 396, 1923.
[2] Breit, *Phil. Mag.*, xlii. p. 832, 1924; Gaviola and Pringsheim, *Ztschr. f. Phys.*, xxv. p. 367, 1924; Eldridge, *Phys. Rev.*, xxiv. p. 234, 1924, and others.

The correspondence principle was formerly enunciated as a rather precise rule by which the results of classical mechanics could be transferred into the quantum theory. There has, however, arisen a tendency to take it in a wider and vaguer sense, as a statement that to any suitable classical theorem there will be an analogue in terms of quanta, and the remaining difficulty is the decision of what theorems are suitable. The present phenomenon strongly suggests a well-known theorem which has not yet been used. A mechanical system vibrating about a state of equilibrium or steady motion usually possesses a unique set of normal modes of vibration, but if some of the frequencies are exactly equal, the modes become ambiguous. Thus a particle vibrating in a plane with equal frequencies for the two directions can describe not only right- and left-handed circles, but also a straight line in any direction. If we apply the correspondence principle to this theorem, it says that if an atom can emit circular waves of equal frequency in either sense, then it can also emit linear waves. We are applying in quite a different branch of the subject Bohr's view of degeneracy, compare it, for example, with his view that in ordinary elliptic motion the eccentricity is not to be quantised, but may have any value.

The accepted form of the quantum theory does not, of course, admit that the same atom can emit both types of circular wave from a given stationary state, but we have seen that it fails to explain the resonance, and the present suggestion is the most natural, if not the only one, which can do so. It must be remembered that there is no direct evidence at all for the emission of purely circular or linear waves from the single atom in the absence of a magnetic field. When there is a field, the degeneracy disappears, the frequencies become unequal, and our theorem is replaced by the straightforward quantum explanation.

There is no avoiding the fact that the theorem has an effect on the quantum theory which is absolutely devastating. Thus there is a failure of all the arguments concerned with the angular momentum of the atom, and therefore of the physical reality of the Bohr orbits. It must, however, be noticed that an idea is entering which is new to the quantum theory, for as the atoms are arbitrarily orientated, the phenomenon requires a definite statement of *phase*. In all previous cases the various linear and circular waves have had unequal frequencies, and so no question of phase arose. There seems to be no reason to give up the concepts connected with angular momentum so long as they are confined to non-degenerate systems or to degenerate systems in which the character of the degeneracy is not studied, and we may expect great further progress by their use. But these concepts are to be regarded, not as ultimate reality, but as a convenient short-cut to the study of complicated systems, and the correspondence principle ought to be applied to the more formal and less physical description of the atom. It is not surprising that the older theory should fail over resonant radiation, for it has shown a complete inability to deal with the other important problem in which phase plays a part, the refraction of light.

It is perhaps possible to argue that a modification might be made in our conceptions of emission without disturbing our ideas of the quantised orbits of the electrons. Even this is not without difficulty, though perhaps it is less insuperable. We have to suppose that the atom is raised to its p-state by the action of the electric force, and that it remains there for a time of the order of 10^{-8} sec. During this time

the precessions and apsidal motions of the electrons will be very large indeed, and it is difficult to see how the atom could, so to speak, remember for so long the axis of the wave it is to emit. Angular momentum would have furnished such a "memory," but the electric force can contribute none about the proper axis.

The discussion is not complete without considering sodium vapour and other substances,[2] but it would take too long to discuss them here. On account of the multiplicity of levels in a magnetic field the effect is more complicated, and the quantum theory is conspicuously successful in explaining the imperfect polarisation, but the difficulty with no field remains outstanding and seems to require the same hypothesis as does the more extreme case of mercury.

May I take this opportunity for a word of personal explanation? At the time that Wood and Ellett were doing their experiments, Prof. Wood very kindly communicated them to me and asked me for an explanation of them. I wrote this back to him in a rough form, making use of a trigger idea for the excitation. I was only regarding this as a quick way of using the classical theory without introducing the fundamental difficulties which lie at the root of it, but I had no opportunity of casting the explanation into a more conventional form in accordance with that theory. I must confess I also had the impression that it would go as well in terms of quanta, but I certainly had no idea either of the special success which would attach to the cases of sodium, etc., or of the difficulty which is the subject of the present letter.

C. G. DARWIN

The University, Edinburgh,
January 2, 1925.

Transmission of Stimuli in Plants.

IN an article in NATURE of October 25 Prof. Dixon [1] has reviewed an investigation of conduction in *Mimosa pudica* which I lately carried out in Trinidad.[2] He agrees with my conclusion that "normal" conduction in the stem has been correctly explained by Dr. Ricca as depending on a stimulant moving with the transpiration current in the wood, but disagrees in that he inclines to consider that Dr. Ricca's explanation is adequate to cover *all* the phenomena of conduction in Mimosa, including conduction in the leaf and the subordinate phenomenon of "high-speed" conduction in the stem. He offers no positive evidence tending to support this view, but criticises the evidence from which I have concluded that Dr. Ricca's explanation will not cover the whole ground.

This autumn, working on *Mimosa Spegazzinii* in Sicily, I have obtained further evidence which confirms my previous conclusion, and provides an answer to several of Prof. Dixon's criticisms, with most of the remainder of which also I am unable to agree. It was found, for example, that in the leaves of cut shoots that had been totally submerged under water for two or three hours, excitation was conducted in both directions considerably *more* rapidly than in similar leaves in air and still attached to the plant. Yet in the stems of such shoots, the velocity of the transpiration current, as measured by ascent of stain, was reduced to about 1 cm. per minute, as against a rate of about 5 cm. per minute in shoots with their leaves in air.

Again, the experiment was repeated of cutting off the tips of leaves under a stain. Previously it was found that in most cases the stain failed to enter the vessels at the leaf tip. The explanation may be that the vessels in some way got blocked, as Prof. Dixon suggests—a possibility that ought certainly to have been taken into account before. But this time the leaves were so manipulated that the stain always entered the vessels. It was, however, sucked back down the leaf at the rate of from 1 to 2·9 cm. per minute only, while in the same leaves at the same time excitation was conducted down at speeds from 6 to 12 cm. per minute.

Similarly, in detached leaves that had stood for some hours with the base of the petiole in water, the rate of ascent of stain was only from 1 to 2 cm. per minute, while at the same time excitation was conducted up them at speeds from 6·2 to 16 cm. per minute. The movements of water in the vessels cannot, therefore, account for excitatory conduction even in the leaf of *M. Spegazzinii*, in which it is much less rapid than in the leaf of *M. pudica*. The results also show that in the leaf the transpiration current ascended much more *slowly* than in the stem, whereas excitation, in *M. pudica* at least, is conducted far more rapidly in leaf than in stem. The details of these experiments it is intended soon to publish.

With regard to Experiment 11, in which all the wood was cut through in the petioles of leaves of *M. pudica*, Prof. Dixon says that it is hard to see why excitation could not have been conducted down by a stimulant passing down the wood and crossing the watery gap. The reason is surely clear. In order to explain basipetal conduction in the leaf by movements of water in the wood, it is necessary to suppose, as Dr. Ricca and Prof. Dixon have supposed, a state of tension in the water columns, which is released by cutting the leaf tip. But in this case, the cut in the petiole had opened up all the vessels to the surrounding water in which the cut was submerged all the time, so that no adequate tension can have existed. It is, therefore, impossible that a stimulant in the water columns should have been sucked back even down to the cut, let alone passing it, as did the excitation, and reaching the main pulvinus, a total distance of about 7 cm., in 3½ seconds. It can only have travelled by the phloem. The conditions were absolutely different from those in the "discontinuity" experiments on the stem, in which a water-tight joint was made between the two portions of stem, in order that the stimulant might be sucked over from one to the other. Moreover, it was pointed out that the next experiment (Expt. 12), which Prof. Dixon does not mention, shows that in preparations consisting of a portion of stem carrying one leaf only, similar to those on which the above experiment also was performed, excitation cannot be conducted basipetally by movements of water in the wood. For the killing of a zone of the petiole by a jet of steam was found absolutely to prevent all basipetal conduction, though acropetally excitation could still be conducted—no doubt by a stimulant moving up in the transpiration current (Expt. 13).

Prof. Dixon does not refer either to the remarkable and more numerous experiments, which I quoted, by Prof. Herbert,[3] who, with a skill much greater than I could provide, had previously interrupted, in various ways, the continuity of the various tissues of the petiole of *M. pudica*, and had concluded that the path of conduction is the phloem. It would be regrettable if proper notice were not to be taken of Prof. Herbert's work, just because he has published in a little-known journal.

Finally, with regard to high-speed conduction in

[2] Ellett, NATURE, December 27, 1924, vol. 114, p. 931.
[1] Dixon, H. H., NATURE, vol. 136, p. 626, October 25, 1924.
[2] Snow, R., Proc. R.S., B, vol. 96, p. 349, 1924.
[3] Herbert, D. A., *The Philippine Agriculturist*, vol. 11, No. 5, 1922.

the stem, Prof. Dixon seeks to explain this as due to a "rupture of the tensile sap" in one or two vessels. In cases in which the cut that set up "high-speed" conduction was found to have reached to the cambium only, and not to the wood, he supposes that the sap in the vessels was ruptured by pressure from the razor upon adjacent cells. He quotes in support certain observations by Böde. Since the cuts were made obliquely and slowly with a sharp razor, there can only have been very slight pressure on the vessels. Further, on looking up Böde's work[4] (p. 101 *seq.*), it will be seen that he does indeed state that pressure from the flat side of a lancet-needle caused bubbles to appear in uninjured vessels of various plants, though strong pressure was needed except in wilting shoots. But he goes on expressly to point out (p. 103) that yet the columns of sap did *not* break. A film of water surrounded the bubbles, which were seen gradually to disappear.

Moreover, my experiments were made on cut shoots, cut under water and rested with their bases in water for at least 1½ hours. No doubt in the upper parts of these shoots there was considerable tension on the water columns owing to the resistance of the conducting channels below. But I find in my notes five cases in which the cuts that set up "high-speed" conduction were made in the basal internodal portion, less than 4 cm. long, below the lowest leaf, including one in which the cut was only 5 mm. from the extreme base, and another in which the cut reached only down to the cambium. In these basal stem portions it is hard to see how there can have been much tension on the water columns. In still another case (Expt. 7) "high-speed" conduction was set up by cutting off a short length from the base of a shoot totally submerged for 3 hours under water. It does not seem possible, therefore, to explain the "high-speed" conduction of the stem either by movements of water in the vessels.

In his letter of January 10, Sir J. C. Bose gives the impression that I have disagreed entirely with his views on conduction in Mimosa. Actually, however, in agreement with him I have produced evidence to show that in the leaf, excitation is conducted in the phloem and has nothing to do with the transpiration current. I agree also that this conduction in the leaf is, in all probability, a true physiological process, and consider that Sir J. C. Bose's experiments on the petiole, which so strongly support this view, are of very great value. In the stem, however, as I found, this conduction in the phloem either fails completely, or at least is regularly too weak to cause the leaves to fall. The result is that in the stem, Dr. Ricca's slower mechanism of conduction by the transpiration current is able to reveal itself. With regard to the "discontinuity" experiment on the stem, it is difficult to take seriously Sir J. C. Bose's suggestion that Dr. Ricca and I both committed the truly remarkable blunder of being misled by a direct effect of the stimulating flame upon the leaves above the water-filled tube. It is impossible that such an accident should have caused a perfectly normal conduction up the shoot, in which the next leaf above the tube did not fall until about 40 seconds after the leaf below the tube. I would refer him to Dr. Ricca's original experiments also, who kept his shoots horizontal. If Sir J. C. Bose has failed to repeat this experiment on the stem, this can only be because his experimental arrangement is unsatisfactory.

The Velocity of Oxidation of the Metals and the Structure of Coloured Oxide Films.

WHILE general opinion ascribes the appearance of temper colours to interference between the light reflected from the outer and inner surfaces of a coherent film of oxide, no very definite proof has hitherto been brought forward that this view is correct, and many opinions have been stated to the contrary. The observation of Mallock (Proc. Roy. Soc. 94A (1918), 566) that the colours are unaltered in hue and only diminished in intensity by grinding away the film, has appeared to many to be irreconcilable with the hypothesis that interference is the cause.

We have recently obtained evidence which we believe to render indisputable the claim for interference. In a series of papers published recently in the *Zeitschrift fur Anorganische Chemie*, Tammann has described experiments in which he made use of the film colours (assuming interference as their cause) to measure the rates of "dry" oxidation of the metals. For many of the metals he found the velocity of oxidation to be proportional to t^{-1} (t being the time reckoned from the moment of first exposure to oxygen), the proportionality factor being dependent on the nature of the metal, its temperature, and on the partial pressure of the oxygen. In the course of a study of the oxidation of zinc, in which the rate of fixation of the oxygen was determined directly, it has been found in this laboratory that the rate of reaction is proportional to $t^{-(1-a)}$, where a is small as compared with unity. While these measurements are not therefore in complete agreement with those of Tammann, the close approximation of the two expressions would appear to constitute a quantitative proof that interference is the true explanation of the colours.

Ill-defined colour changes were occasionally noticed in the experiments on zinc described, but since it was necessary to sublime the metal *in vacuo* (to free it from occluded gases), no estimate could be made of its surface area. C. N. Hinshelwood, however, (Proc. Roy. Soc. 102A (1922), 318) gives data for the oxidation of copper from which it is possible to make a comparison of the amounts of fixed oxygen (which he determined directly) with the thicknesses of the films as estimated from their colours. Assuming the oxide formed to be cupric oxide, Hinshelwood gives the following data:

Gm. of CuO per sq. cm. of Copper Foil	Colour of Film
0·000030	Purple
0·000043	Blue
0·000073	Light Green

If, as the interference theory would require, the oxide forms a coherent film which clings tightly to the metal, Tammann is almost certainly correct in supposing that the oxide primarily formed on copper is cuprous and not cupric oxide. For while in the space-lattice of the lower oxide the copper atoms are arranged precisely as in the metal itself, and at nearly the same distance apart (so that the passage from the metal to this oxide can take place with a minimum of disturbance) the higher oxide has a much more complex structure which could only be formed by the breaking up of the original lattice-pattern. Taking the density of cuprous oxide to be (roughly) 6 gm./c.c. and its refractive index as 2·7, the thicknesses of the air-films which should give colours corresponding to those shown by cuprous oxide films containing the above amounts of oxygen per sq. cm.

are calculated to be, respectively, 243, 348, and 590$\mu\mu$. Referring, for example, to the Landolt-Bornstein "Tabellen" for the colours characteristic of air-films of about these thicknesses, one finds the following

257$\mu\mu$ Purpur { 300$\mu\mu$ Himmelblau / 352 Heller Himmelblau } 600$\mu\mu$ Meergrün

If interference were not the cause of the phenomenon, it would be a sufficiently curious coincidence that the thicknesses calculated should come *at all* within the range of those giving rise to Newton's colours.

Hinshelwood remarks that successive oxidations and reductions of a copper surface led to an intensification of the film colours produced, and to a correspondingly greater rate of fixation of the oxygen. He showed that the amounts of oxygen required to form films of the above colours remained in constant ratio. The simplest explanation of these facts would appear to be that the treatment causes a roughening of the surface, whereby the effective area of the metal is increased. If this should prove to be the case, it would provide a not unlikely explanation as to why the colour remains unaltered when the outermost surface is ground away.

Stonehenge: The supposed Blue Stone Trilithon.

I have read with much interest the review which appeared in the issue of Nature for November 1, headed "Archæology of Stonehenge," not only as a thoughtful criticism on my recently published work, but also as a valuable up-to-date addition to the literature on the subject.

The matter of the supposed Blue Stone Trilithon is of some importance in regard to the design of Stonehenge. It has been commonly supposed that the two cup-shaped hollows now to be seen in Stone No. 150 may be mortise sockets, indicating that the stone had been the lintel of a miniature trilithon. In my book I have discussed the subject in some detail, and have given references to authorities and a photograph of the stone. The conclusion arrived at is that these cup-shaped hollows have nothing to do with the original design of Stonehenge, but may very likely have been mortars for grinding grain, formed, perhaps, by prehistoric squatters on the site long after the building of Stonehenge, when the structure was already in a partly ruinous condition.

In reference to this the writer of the review remarks.

> "The author is in error over a fallen foreign stone which figures in Plate 6, Fig. 2, in supposing the two holes seen on it were made, after it had fallen, . It is curved in the same way as are those of the outer circle, but in this one the curve is sharper, showing it belonged to something smaller. The holes in the stone are equidistant from the ends and are dowel holes like those in the big lintels, and this stone may formerly have fitted over the terminal upright stones of the horseshoe."

As a matter of fact, the centres of the hollows in the stone are *not* "equidistant from the ends." The one towards the north is 2 ft. 6 in. from that end of the stone and the other is 1 ft. 11 in. from the farther end. The distance centre to centre of the hollows is only 3 ft. 5 in., and if a drawing be made to scale showing two of the obelisk-shaped stones of the horseshoe at this distance apart (centres), with this supposed lintel on top, it will be seen that the two uprights would have to be not much more than a foot apart in the clear (instead of the normal clearance of four or five feet). The tail-end of the (supposed) lintel would moreover have a considerable unsymmetrical overhang beyond its upright. Such an abnormal arrangement is of course possible, but from what we know of the work of the builders of Stonehenge it may be regarded as most improbable.

An attempt to form a trilithon with this stone as lintel supported on two of the shapeless boulders of the blue stone circle would be found even more impracticable.

It is to be noted, moreover, that the face in which the hollows appear is not even, and the hollows are askew with each other (see Fig. 1). The stone has a considerable curvature which would unfit it for a place at the end of one of the straight limbs of the horseshoe. This curvature is double (slightly S-shaped), and is merely the form of the original boulder. It is not dressed, and has therefore no significance.

It will further be observed that among the blue stones remaining on the site there is no stone that has any sign of a tenon on its top, or which bears any indication that it may have been an upright for a trilithon—nor is there any other stone which has cup-shaped hollows like those on Stone No. 150. All the blue stones (now remaining) are, moreover, exceedingly hard (diabase and rhyolite) and show no sign of weathering.

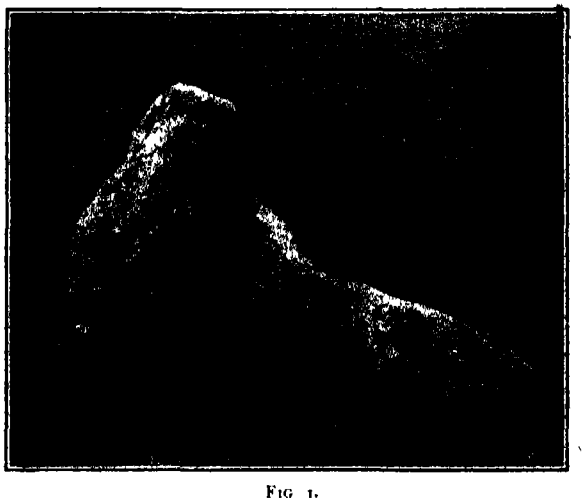

Fig. 1.

On the evidence of the physical facts noted above, and from other considerations set forth in my work on Stonehenge, it may be regarded as extremely improbable that Stone No. 150 could have been the lintel of a trilithon. It will, moreover, doubtless be agreed that if this stone had been dug up in the course of excavation on the site of a prehistoric village, the conclusion that the hollows were mortars for grinding grain would have been accepted as obvious.

Mr. Edward T. Stevens, the eminent Wiltshire archæologist, writing on this subject in 1876, remarks as follows:

> "The two cavities in the prostrate foreign stone are too far from the ends of this particular stone, and too close together, to justify one comparing it with the imposts of the outer circle or outer horseshoe. No trace remains of either of the syenitic uprights upon which it rested. This stone, however, is quite as likely to have served for an altar as for an impost, and the cavities may have been intended to receive libations or offerings of some kind."

Stevens then goes on to describe similar stones found in Sweden known as "elf-stones," which are still held in superstitious veneration and receive offerings to ward off sickness. He adds: "I venture to suggest, therefore, that some further attention be given to this subject, before we jump to the conclusion that this foreign block of stone was an impost" (Jottings on the Stonehenge Excursion, August 1876, pp. 133-138.)

E. HERBERT STONE

The Retreat, Devizes

The Word "Scientist" or its Substitute.

WHEN literary gents, like Sir Clifford Allbutt, Prof. D'Arcy Thompson and Sir Israel Gollancz, come forward in defence of *scientist* and Sir R. A. S. Paget, an expert in vocal sounds, in the most cold-blooded manner possible, says that he would *ist* everybody, it were time that we illiterate sciencers ranged ourselves solidly with Sir Ray Lankester, ever a defender of the faith, proclaiming that we will not have truck with the would-be debasers of lingual beauty.

If I had ever favoured the term—I hate it—I should cease from using it, if only after listening to the High Commissioner for Australia, at the Imperial College of Science (not yet Scientists) dinner, a few days ago. Replying for the guests, at the close of his speech, he referred to the story of two men talking together and one saying—"There will be nothing to laugh at fifty years hence." "What, will there be no scientists!" came the reply. Let us hope there will not be any. The story is a good exemplification of our form in the public eye.

The real men, those who do things—bakers, butchers, builders, boxers, grocers, even green-grocers—all have names ending in *er*. The terminal *ist* is reserved for theosophists, thaumaturgists, even for those who pretend to be but are not chemists, only bits of the same. So far, indeed, is objection taken to chemist that a wag among them has proposed to substitute *chemor*, not chemor-ist, be it noted. The German *chemiker* was long known as superior to the English *chemist*. Still, *er* has its weak side to some—I am told that, in New York, the undertaker seeks to be known as the mortician. The fact is, none of us likes his name.

The Oxford Dictionary, a mine of inspiration which is too little used, gives *Sciencer* and *Sciential*, both euphonious words. Of late, I have often used sciencer, and like it. Sciential has the authority of Keats and is less committal—it may even be applied not merely to the properly scientific but also to those who neither do nor make anything but merely talk and claim to be of the elect, though I should bar classical telepathists. As to Dr. Jeans, for whom solicitude is properly expressed, he may well be spoken of as a sciencer, if not reckoned with magicians all will devoutly pray that he be kept away especially from *ists* in the guise of psychists.

I write this without consulting my sons but believe they would all support me, though I have not gifted any one of them with a musical ear—one of them, however, was brought up under Sir Clifford Allbutt in days when he was the boldest of warriors in defence of our English tongue.

We shall do well to take notice that scientist is fast becoming a word of evil import in the public ear—as meaning one of the set of peculiar people who talk a language no fellow can understand. Some day, soon, perhaps, the call may come to label NATURE: the Journal of Babel; the Dictionary will then give—Babel, the language of a sect devoted to an obscure practice known as science.

HENRY E. ARMSTRONG

SCIENTISTS have hesitated to use the word "scientist," not because it is a hybrid (they are well used to hybrids), nor because it ends in a sibilant "-ist" (they are most of them "-ists," of one kind or another); nor because the word is appropriated by the unqualified (professors are inured to such treatment), nor yet because the word was originally used opprobriously (they are not really less courageous than Tories or Radicals), but because they were diffident. They feared to offend classical taste. No scientist ever puts his pen to paper without casting a fearful glance over his shoulder to see whether a classic should be looking on. You may reproach a classic with ignorance of science and he will plume himself with the compliment. But to suggest to a scientist that he is guilty of a classical lapse is more mortifying to him than to tell him he should have said "napkin" instead of "serviette." It is thus sheer nervousness which has prevented him from using a generic term as obvious and inevitable as is the word "artist." Now, thanks to you, the scientist is discovering, with something of the naiveté of M. Jourdain, that the classic never dreamt of objecting to the word and only wonders why there should be so much shyness about the use of it.

Gray's Inn, W.C. 1.

Anomalous Dispersion in the Field of X-Rays.

IN the course of an investigation with the purpose of getting more exact determinations of the wave-lengths of the X-ray spectra, we have carried out a comparison of the lattice-constants of the two crystals, calcite and gypsum. In order to find the best possible value of this fundamental relation, we used a series of different spectral-lines with wave-lengths varying from 0·7 up to 5·2 Å.U. The measurements of the relation are given graphically in Fig. 1, where the values of $\frac{d_1}{d_2} - \frac{\sin\phi_2}{\sin\phi_1}$ are plotted against the wave-lengths. As seen from the graph there are two

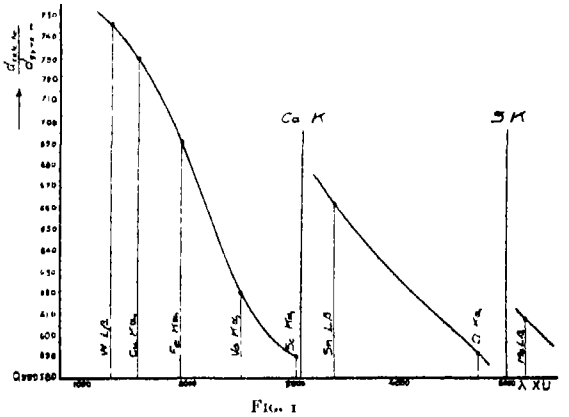

FIG. 1.

marked discontinuities in the run of the curve. It is also seen that these two abrupt variations coincide with the wave-lengths of the absorption-edges of calcium and sulphur.

It may be seen from the theory of X-ray reflection by crystals as given by Darwin and Ewald, that such an anomalous dispersion is to be expected. From these theories it is known that the simple Bragg law of reflection

$$n\lambda = 2d \sin\phi$$

is still valid if we give a modified meaning to the

constant d, that is, if d means, not the true distance d_0 between the reflecting planes but a corrected value

$$d = d_0\left[1 - \frac{4d_0^2}{n^2}\frac{\delta}{\lambda^2}\right],$$

where δ has the value known from the ordinary dispersion-theory.

$$\delta = \frac{e^2}{2\pi c^2 m}\sum_{s=K,L,M}{}' \frac{N_s}{\nu^2 - \nu_s^2},$$

and ν_s are the natural frequencies of the K, L, M, etc electrons

On passing one of the natural frequencies, the value of d apparently undergoes an abrupt variation quite in accordance with the experimental results

It may be noticed that the graph is not a simple dispersion-curve, as it gives the relation between *two* such curves, namely, that of gypsum to that of calcite. The discontinuity at calcium is due to the fact that the relative number of the K-electrons of this element per unit volume is different at the two crystals

This result shows that it is necessary in all accurate measurements of X-ray wave-lengths to use a corrected Bragg formula for the calculation of the wave-lengths from the angles of reflections For this purpose, the first condition is to know the dispersion formula of the crystal for X-rays Such an investigation may be carried out with the ordinary prism-method applied for X-rays, as shown in a communication from this laboratory (*Die Naturwissenschaften*, December 26) or with the method given by Bergen Davis and his collaborators

Upsala Universitet,
December 12

Scattering and Absorption of γ-Rays.

IN a recent letter to NATURE (January 3, p. 13) I have stated that, on current theories, it is exceedingly difficult to account for the results of experiments on the scattering and absorption of hard γ-rays. I should like to add to this statement that a reasonable explanation of such results has since been obtained by means of the following assumptions, for which there is a certain amount of evidence

1 The secondary β-rays produced in light elements by hard γ-rays are practically all recoil electrons.

2 The photoelectric or fluorescent absorption coefficient of γ-rays varies as the cube of the wave-length

3. The hard γ-rays of radium-C behave in the same manner as would a mixture of two types of wave-lengths 0 024 and 0 008 Å U. respectively, each type having about 50 per cent of the total energy

4 The number of quanta scattered per unit area at an angle θ varies as $(1+\cos^2\theta)/(1+2\alpha)$, where $\alpha = h\nu_0/mc^2 = 0\ 0242/\lambda_0$, h being Planck's constant, ν_0 the initial frequency, m the mass of an electron, c the velocity of light, and λ_0 the initial wave-length.

With the angular distribution of "scattered" quanta proposed above, the average energy of a recoil electron, for values of $\alpha > 1$, approaches closely the maximum energy E_M which equals $2\alpha h\nu_0/(1+2\alpha)$ Further, as α increases, the total energy of the recoil electrons becomes a greater and greater proportion of the energy lost by the scattering process, *e.g.* when $\alpha = 3$, the total energy of the recoil electrons is equal to twice the energy of the scattered γ-radiation. These are the reasons why one can account for the observed energy of the secondary β-rays when it is assumed that a large proportion of the total γ-ray energy is of the softer type, it being necessary to assume that this type is present in order to account for the observed values of the fluorescent absorption coefficient

It might be mentioned that, with distributions of scattered quanta hitherto proposed, the average energy of a recoil electron is about $\frac{1}{2}E_M$, and the total energy of the recoil electron is always less than that of the scattered γ-radiation.

I believe it can be shown, from what has been proposed above, that γ-rays must have a "range"; *i.e.* for rays of any one wave-length, there could be a certain thickness of material, through which the rays would not pass, no matter how great the initial intensity. This would indicate that the scattering of γ-rays is a scattering of "corpuscles," a view which I referred to and rejected in a former paper (*Phil. Mag.*, p 611, 1913)

In my letter of January 3, p. 13, it is stated that, "Taking the average energy of such a β-ray to correspond to 467,000 volts, . . a simple calculation shows that only one in every five radium-D atoms emits a γ-ray on disintegration" The figures should have been 333,000 volts and only one in every seven radium-D atoms emits a γ-ray on disintegration

J A. GRAY.

Queen's University,
Kingston, Ontario

Spermatogenesis of *Succinea ovalis*, Say.

AN investigation of the spermatogenesis of *Succinea ovalis*, Say., a small terrestrial pulmonate of North America, has revealed the following

1 Forty chromosomes are found in the spermatogonial divisions, and twenty in the maturation divisions

2 Typically of all pulmonates so far studied, there are two centrioles, proximal and distal. Early in spermogenesis the proximal centriole penetrates through the nucleus of the spermatid, and with the surrounding intranuclear canal, forms an intranuclear rod in very much the same way as has been reported for certain prosobranchs

3. Both the head and tail of the spermatozoon have a spiral twist. These spirals go in either a clock-wise or counter clock-wise direction, one type being about as common as the other.

Of the cytoplasmic structures, the mitochondria and the Golgi apparatus were followed through all stages of spermatogenesis

The mitochondria are seen in the early primary spermatogonia as small masses of granules lying near the nuclei. They increase in size and number in the primary spermatocytes, and at each of the maturation divisions they are distributed approximately equally between the daughter cells. Some of the granules go to form the sheath of the axial filament of the spermatozoon, while the rest are sloughed off with the cytoplasmic balls.

The Golgi rods cannot be identified with certainty in the primary spermatogonia. In the primary spermatocytes they occur as conspicuous banana-shaped rods grouped closely around the idiosome; 15-20 rods can be counted in these stages. During dictyokinesis there is no fragmentation of individual rods, but they are distributed intact to the daughter cells 3-5 rods are found in the spermatids. In the final ripening of the spermatozoon, the apparatus is seen in the cytoplasmic balls as faintly-staining, disintegrating bodies.

A more detailed account will be published later.

Biographical Byways.[1]

By Sir ARTHUR SCHUSTER, F.R.S.

3 BALFOUR STEWART (1828–1887)

IF I were asked to name Balfour Stewart's outstanding quality as a scientific investigator, I should designate his absolute freedom from preconceived ideas both in the selection of his subjects and the manner in which he treated them. He was fond of arguing by analogy or familiar illustration. According to the writer of his obituary notice in the Proceedings of the Royal Society, who knew him intimately, he was "full of the most weird and grotesque ideas." I cannot say that I ever became conscious of this in my own intercourse with him, but I only came into contact with him after his slow recovery from the injuries sustained in the Harrow railway accident of 1870. He was not a good lecturer and had difficulty in keeping order in the lecture-room—perhaps it would be more correct to say that he did not take the trouble to keep order, being too sympathetic with youthful exuberance. In the laboratory he was an inspiring teacher, and it would not be an exaggeration to say that he was the godfather of much of our modern science, both Poynting and J. J. Thomson having received their first lessons in physics from him.

Balfour Stewart's family intended him for a mercantile profession, and at the conclusion of his university studies he spent some time in Australia. But science had laid its spell on him, and he soon returned to Edinburgh, where he became assistant to J. D. Forbes, who had considerable influence in shaping his mental outlook. It was during the six years he spent at Edinburgh that the work on the equilibrium of temperature radiation was begun and, in its essential features, completed. In 1859, Balfour Stewart was appointed superintendent of the Kew Observatory, which was then managed by a committee of the British Association under the presidency of P. Gassiot. All went well until the organisation of the meteorological service of the country was transferred from the Board of Trade to a committee of the Royal Society, consisting of eight Fellows, with General Sabine as chairman. The expenses were covered by a Treasury grant of 10,000*l.*

Trouble soon arose, and, I think, both for their historical interest and in justice to Balfour Stewart's memory, an account of the incidents which ultimately led to his retirement from the directorship of Kew Observatory should be given. I am enabled to do so on the evidence of the relevant documents, which came into my keeping after Balfour Stewart's death. When the Board of Trade had agreed to the request of the Meteorological Committee for the assistance of a scientific secretary, Balfour Stewart was appointed to that office, understanding that he was to be the scientific adviser of the Committee; but when afterwards he was designated simply as "Secretary to the Committee" he disliked the omission of the qualifying word "scientific," but acquiesced. "Nevertheless," he declared in a printed statement from which I quote, "I continued to understand that it was my special duty, in case I might see anything defective in the scientific position of the Committee, to urge them to amend it."

[1] Continued from p. 57.

Differences of opinion soon arose between Sabine and Stewart with regard to the method of reducing meteorological observations, and his repeated requests for clerical assistance were declined by the Committee. The crisis came when Balfour Stewart directed General Sabine's attention to what he considered to be an error in an unconfirmed minute of one of the meetings of the Meteorological Committee. Stewart's account of the interview which took place concludes with the following statement: "He [General Sabine] assured me there was no mistake and added in answer to a question that he, *on his own responsibility*, had authorised the preparation of such of those results at the central office as had not been authorised by the Committee." To use a familiar term, Sabine admitted having cooked the minutes. At the same time, Balfour Stewart was privately told that the chairman was much opposed to his scheme of reducing observations, and that there was not much chance of its being adopted. With regard to the merits of the proposed scheme there can be little doubt. Stewart had submitted it to a few independent men of science and the reply of the Astronomer-Royal, Sir George Airy, may be given *in extenso*:

> "I have read with much satisfaction the paper of your Remarks on Meteorological Reductions, etc., especially with reference to Vapour. I do hope that by going on thus you may make Meteorology a science of causation, and raise it from its present contemptible state.
>
> "I have often thought that much may be gained by ascertaining at what rate aqueous vapour disseminates itself through air, and should long ago have made experiments, but that I want a hygrometer of sufficient delicacy. I then thought of suggesting it to the Kew Committee. Your paper restores the interest in my old intention, and I think I shall write to Mr Gassiot."

Lord Kelvin (then Sir William Thomson) also gave his full approval, writing:

> "I believe the plan you propose is adapted to bring out information of the most valuable kind, from observations which, until reduced on some such plan, might be accumulated indefinitely without any practical benefit."

Stewart was naturally distressed by the manner in which his advice was set aside, no scientific grounds being given. Fearing that the anxieties of his office might affect his health, he wrote a letter to the chairman of the Committee resigning the secretaryship. He also tendered to Mr. Gassiot his resignation as superintendent of Kew on the ground that the two bodies were closely bound together, but declared at a meeting of the Meteorological Committee that he gave up this office with extreme reluctance. He was asked, in an interview with Mr. Gassiot, whether there was anything that would induce him to withdraw his resignation, and was given to understand that Sabine would wait to hear the condition under which he would continue office before taking further steps. Stewart then wrote a letter explaining the difficulties

in which he was placed owing to insufficient help in the numerical work and stating that, if some assistance were given him in the preparation of the preliminary reductions of the observations, he desired to withdraw his letters of resignation. The reply was as follows:

"I regret that you were so determined to send in your resignation It appears Sir Edward Sabine has written to Bombay, where Colonel Smythe is, and nothing can be done until the reply comes."

Sabine's letter referred to, offering the appointment to another man, was posted on the day of the interview with Gassiot, and as Stewart points out—before his resignation had been formally accepted by the respective committees

The obstinacy with which Sabine pressed his own opinion is perhaps intelligible in a man who was then eighty-one years old, but there is nothing to say in extenuation of the want of generosity exhibited in the following letter to Stewart:

"My not having responded to your request more promptly and more fully, has not arisen from want of solicitous thought, and wish to serve you.

"I feel assured that if your work at Kew had ere now been crowned by the looked-for completion of the account of the results of the long and invaluable series of magnetic observations, the later and longer portion of which were under your own superintendence, you might, and I might, have appealed triumphantly to such an evidence, not only of what you were capable of doing, but of what you had done, as placing you in a pre-eminent position"

The letter is dated May 31, 1870, and was presumably written in answer to a request for a testimonial in view of Stewart's candidature for the chair of physics at Owens College, Manchester With regard to the implied complaint, I have before me the copy of a letter written by Balfour Stewart, from which it appears that he was waiting, previous to 1865, for the details of the observations which were in Sabine's possession In spite of his repeated requests they were never sent to him. He could scarcely be expected to start on an extensive work of reductions before he had the whole material before him.

Balfour Stewart's greatest scientific success was achieved in his researches on the equilibrium of radiation in an enclosure of uniform temperature, which led to the enunciation of the connexion between radiation and absorption. His omission to drive home convincingly the application of his results to the explanation of the dark Fraunhofer lines was, in his own later opinion, due to a want of chemical knowledge Looking at a flame coloured with common salt, and believing that the yellow colour of the flame was due to luminous sodium chloride, he was disappointed to find that a plate of rock salt did not sensibly absorb the emitted light

Stewart had the faculty of recognising the importance of problems, even when he had not the power theoretically or experimentally to make much headway in their solution. He saw, for example, the need of studying the temperature equilibrium in an enclosure which contained moving bodies, both radiation and absorption being affected by the Doppler effect. But instead of looking for the solution of the difficulty—as was subsequently done by Wien—in an adjustment of the law of radiation as depending on temperature and wave-lengths, he imagined that the equilibrium of radiation was actually destroyed, the second law of thermodynamics being satisfied by the mechanical forces necessary to maintain the motion. In conjunction with Tait he designed an experiment in which a disc was kept rotating *in vacuo*, and believed he had actually discovered an increase of the temperature of the disc The success of the experiment depended of course on the perfection of his vacuum, and Stewart shared the erroneous belief of the time that a perfect so-called chemical vacuum could be obtained by filling a vessel with carbonic acid, exhausting with an ordinary air pump and absorbing the remnant of the gas with caustic potash.

I have remarked that Stewart's mind worked a good deal by analogies He was fond of one particular illustration Imagining a moving train and a body of men cutting across by jumping into it from one side and out of it at the other, it is clear that the train will gradually lose speed The idea was applied to special cases and suggested several experiments to him. I joined him in one of these, in which an electric current was passed through water and an electromotive force applied at right angles to the current Stewart hoped to detect some interference of the currents with each other The same type of reasoning was in his mind in contemplating possible mechanical effects of radiation I believe that at the bottom of these speculations was some prophetic glimmering that a propagation of energy always implies a propagation of momentum. The weak feature of his work was, that he often designed and tried experiments of a refined nature with appliances which were insufficient, and even at that time might have been improved upon—such were his attempts to discover a screening effect of metals on gravitation, or a change of mass by chemical combination In the latter experiments, in which the combining bodies were mercury and iodine sealed up in a glass bottle, J J. Thomson, who assisted him, nearly lost his eyesight through an explosion.

Stewart was indefatigable in his work While the days were spent in the laboratory, he pursued his statistical investigations on magnetic and solar phenomena in the evenings. Some of these researches are published under the joint names of himself, De la Rue and Loewy. The latter gentleman—though I believe he had some claim to scientific knowledge—was chiefly employed as an assistant, paid for carrying on the numerical work, which was often heavy. I believe that De la Rue's share consisted in supplying the funds. One morning Stewart arrived at the laboratory in a great state of distress. In looking over the proofs of a paper accepted for the Philosophical Transactions, he had found that the numerical work was all wrong. Loewy had, in fact, saved himself trouble, and evolved the results out of his inner consciousness. The paper had to be withdrawn, and De la Rue paid a substantial sum for the expenses already incurred in printing. Neumayer, who was at the time director of the "Sternwarte" at Hamburg and on whose recommendation Loewy had been engaged, told me afterwards that he had sent for Loewy and charged him with manipulating the results. Loewy admitted doing

this, but excused himself on the ground that, while he had originally worked honestly, Stewart had never checked his results, so that the blame must be his

Some reference should be made to a little volume, "The Unseen Universe," published in 1875, and intended to reconcile science with revealed religion It appeared anonymously at first and, though probably forgotten now, it created a sensation at the time, running rapidly through many editions, in the later ones of which the authors' names -- Balfour Stewart and P. G. Tait—were given Referring to Tait's contribution, Stewart told me that when he first approached him, suggesting a joint publication, his consent was subject to the condition that Stewart should write the book while he would make himself responsible for the preface When this was agreed to and the manuscript of the preface arrived, Stewart was amused to find that it was almost entirely taken up with an attack on John Tyndall, who was Tait's *bête noire* It had to be re-written, and to judge from internal evidence I should surmise that not much more than the first paragraph was Tait's work I am under the impression, nevertheless, that Tait's share in the book was not negligible, and that though he acted mainly in an advisory capacity at first, he made substantial additions in the later editions.

Towards the close of his life Stewart became much interested in so-called spiritualistic phenomena, but he always insisted —sometimes with great vigour—on his disbelief in messages from the dead, which were contrary to his religious convictions With regard to unexplained phenomena, in which fraud may possibly have a share, it must be said that Stewart's confiding nature rendered him quite unfit to act as a judge He was like a child in these matters. A certain personage near Buxton —so far as my recollection goes, a clergyman—wrote to Stewart about his powers of second sight, which enabled him to find a hidden object or name a card drawn at random out of a pack. Stewart went to see him several times and was impressed. "What is most remarkable," he told me after the second or third visit, "is that the power can be transferred to others There is a servant girl in the house who, after a stay of a few weeks, has acquired it and can now name an unseen card just as well as her master" Not a shadow of suspicion had crossed his mind

Stewart's conversation was always suggestive and sometimes witty The Principal of Owens College had a habit of writing letters to the professors when he had any fault to find These always began with some complimentary remarks, the sting being reserved for the concluding sentence, or frequently a postscript "Every billet has its bullet" was Stewart's comment after receiving one of these communications.

The Theory of Evolution since Darwin.[1]

By Prof E. W MACBRIDE, F R S

THE most recent development of the doctrine of evolution is the revival of Lamarckism—that is, the belief in the inheritable nature of the effects of use and disuse Just as Bateson in 1894 enunciated the doctrine of the origin of species by sports long before this view was consecrated by the experimental labours of De Vries and given the name of the "mutation theory," so Eimer (1887) and Cope (1888) rebelled against the Weismannian conception of an unalterable germ plasm totally independent of the effects of the experiences of the body Eimer put forward the doctrine of orthogenesis. This theory states that variations are the results of the effects of the environment on the complex constitution of the living organism, but that this constitution determines the character of these variations; they are not indefinite, but take place in a few definite directions. Eimer, who chose for his special subject of observation the wall-lizard *Lacerta muralis*, and later the swallow-tailed butterflies, pointed out that new variations make their first appearance in the later stages of growth and become inherited earlier in life as the generations succeed one another. A beautiful example, he explains, is afforded by the Ammonites, in which new features are first distinguishable in the outer coil of the shell, which is, of course, the youngest and latest to appear, whereas in succeeding strata the new feature is found affecting the more central coils. Thus it will be observed that Eimer draws the most decisive support for his theory from palæontology. Eimer seems to suppose that he is an opponent of Lamarck, but the only difference between them that I can discover is that Eimer seems to regard external conditions as altering the hereditary tendencies by direct action as sulphuric acid acts on metal, whereas Lamarck considers that external conditions stimulate an organism to make a response, and that it is this tendency to response that is inherited

Cope, in his book "The Origin of the Fittest," likewise advocates the inheritance of the effects of use and disuse, and relies on palæontological evidence to support his view He points out that if the development of the Ungulates during the Tertiary period followed, we find evidence that the shocks and strains to which the leg bones were subjected, and which in moderation create enlargement and strengthening of those bones during the lifetime of the individual, gave rise, as generation succeeded to generation, to permanent thickenings, fusions, and elongations of these bones; and that the modifications in teeth can likewise be explained as reactions to the changing character of the food by which the Ungulata were supported Cope's views have become increasingly prevalent amongst North American palæontologists, and are almost universally accepted by them to-day

The first great blow to Weismannism was delivered by the cytologists and experimental embryologists The foundation stone of the "germ-plasm" theory was the fundamental distinction between body cells and germ cells, and the theory that, as development proceeded, the body cells were specialised so that each could only give rise to its special part of the body. But Driesch showed (1900) that if certain segmenting eggs were fragmented, a piece so small as one-eighth of the whole could give rise to a complete embryo, and Hertwig and Driesch further proved that the arrangement of these cells could

[1] Continued from p. 55

be entirely altered by pressure, so that cells which normally gave rise to the front or back were displaced to the sides, and yet that perfectly typical embryos were formed. More exact methods of investigation showed that the structure of all the nuclei in the body was alike, so that each cell might be regarded as a potential germ cell, and that the differentiation of the organs of the body was not accompanied by a differentiation of the nuclei but was due to local changes in the protoplasm. Therefore the same kind of nucleus—if the nucleus was to be regarded as the fount and director of life in the cell—must respond differently to different stimuli in different parts of the body

Previous supporters of Lamarckism had assumed the necessity of the inheritability of the effects of use and disuse in order to account for changes which could be shown to have occurred, but it was not until 1908 that definite experimental evidence was adduced to show that changes artificially induced had, as a matter of fact, been transmitted to posterity If this evidence were accepted, it was clear that the whole status of the questions must undergo a profound change, for a *vera causa* for the production of functional variations—in a word, of adaptations—would have been discovered. We have seen that strong evidence has been brought forward to show that minute differences distinguishing brothers and sisters of the same family were not inheritable, while "mutations" or "sports" were strongly inherited These sports are, however, invariably pathological or monstrous in character, and if they occurred in Nature would have no chance of surviving or propagating their like

The evidence in favour of Lamarckism was based on experiments with salamanders and toads which were carried out in Vienna There exist two kinds of salamander in Europe, and one of them gives rise to only two young which at birth resemble their mother. The gilled fish-like larval stage with which the typical amphibian begins its free existence is in this salamander passed over within the womb of the mother The colour of the skin is black and the animal lives on the cool Alpine uplands—it is named *Salamandra atra*. The other species of salamander is marked with bright yellow spots on a black background; it is an inhabitant of the lowlands and it gives birth to a considerable number (about thirty) of gilled young, which live for six months in the water before the gills drop off and the animals come on land. This species is named *Salamandra maculosa* Now Dr. Kammerer, the investigator who performed these experiments, showed that if *Salamandra atra* was gradually accustomed to living in warmer and moister conditions, as reproductive period succeeded to reproductive period, it produced more young at an increasingly earlier period of development, and that when these young were reared to maturity and allowed to pair, the second generation gave rise to about half-a-dozen gilled young which took to the water and acted like the larvæ of *Salamandra maculosa*. Conversely, if *Salamandra maculosa* were made to live in comparatively cool and dry conditions, it began to carry its young for longer periods in the womb; fewer were produced at a birth, but these were born at a more advanced state of development. Finally, when these were reared to maturity and allowed to pair, the second generation gave rise to only two or three at a birth, and these were provided only with vestigial stumps of gills, so that they at once took up a terrestrial life.

If, again, the young of *Salamandra maculosa* just after metamorphosis were reared in cages the walls of which were painted yellow and black respectively, in those confined in yellow cages the yellow spots extended in area as the animal grew to maturity, so that after four years they were arranged in two conspicuous rows along the back. If two such animals were allowed to mate and produce offspring, when the resulting generation grew to maturity under the same conditions as did their parents, the yellow extended to such an extent as almost to suppress the black pigment. Those salamanders, on the contrary, which were reared in the black cages contracted the area of their yellow spots as they grew up; and when the second generation were reared under similar conditions, the animals became almost, if not quite, as black as *Salamandra atra* The full effect, therefore, required two generations exposed to the same conditions to show itself, and the second generation started, so to speak, where the parents left off. If the offspring of salamanders which had been reared on a yellow background were reared on a black background, the yellow spots increased in area during the first six months of the animal's life; only after this period did the black begin to gain the predominance, in a word, the animal during the first period of its life *recapitulated* the history of the previous generation This experiment constitutes, so far as I can determine, the first experimental proof of the biogenetic law which has ever been made When the offspring of salamanders which had been reared on a black background grew up on a yellow background a unique effect was produced: the animals developed a single median stripe of yellow on the back This is a form which is practically never found in Nature and can only be produced by experiment.

If we now turn to the experiments on toads, we may observe that nearly all toads, like the frogs, pair in water in the spring-time The male embraces the female with his forearms and keeps her firmly in his grasp for a considerable period—often for weeks—until she emits her spawn, which he then fertilises. In order to enable him to retain a firm hold of his partner's slippery body, he has developed under the index finger a horny pad covered with minute asperities, the so-called nuptial pad. Now Alytes differs from all other toads in that pairing takes place on land, and as the female's body is comparatively dry and thorny the male does not require a nuptial pad in order to enable him to retain a hold on her. The eggs are fewer and larger in size than are the eggs of other toads; but as in other species, they are emitted in a string connected together by a cord of jelly. The male winds these cords round his legs and remains encumbered with them until the young tadpoles hatch out, a curious habit which has earned for him the name of "midwife toad." The tadpoles of ordinary toads emerge from the egg provided with three feathery gills on each side; as they grow these gills become covered over with a fold of skin proceeding from the head, and the larvæ assume the familiar form of a rounded body and flattened tail characteristic of

the tadpole. The tadpoles of Alytes, however, pass through the stage with external gills whilst still within the egg-shell and emerge only when the body has become, as in the later toad-tadpole, rounded and plump. Whilst in the egg-shell they have only *one* external gill on each side.

Now Kammerer showed that although Alytes normally lived in cool spots, it could be induced to live at a warm temperature if it were provided with a basin of water in which to lave itself. In these circumstances, however, the male and female paired in water, and the eggs slipped off the legs of the male and lay in the water. By taking special precautions to keep the water aseptic, some of these were hatched and the resulting tadpoles reared to maturity. The next generation reared under similar conditions produced more numerous eggs which were smaller than those of the normal Alytes. Out of these eggs the tadpoles hatched in the external gill stage with one external gill on each side. In the next generation reared under similar conditions the tadpoles were provided with three external gills on each side as in ordinary toads, and in this generation the males developed horny pads.

These experiments aroused a quite different kind of criticism from that which had been evoked by any previous work, and one which strongly recalled the "odium theologicum" with which the first presentation of Darwin's theory of evolution was received in 1859. The experiments were admitted to be conclusive if true, but some critics declined to accept them. Kammerer visited England less than two years ago, bringing with him critical specimens, amongst them salamanders with a median stripe of yellow and a male Alytes showing the horny pad. Even then the critics were not convinced. It was asserted that the pad in the normal frog or toad was on the upper side of the hand and not on the lower side, and that therefore the specimen produced had not a true horny pad. In answer to this Kammerer asserted that in his Alytes—as his critics would have seen if they had examined it carefully—the nuptial pad was developed on the dorsal surface of the fingers but extended also round to their palmar surfaces, and to this answer I can add that the first four male frogs which I examined after this discussion all showed the pad on the lower surface of the hand as well as on the upper. But Kammerer showed other specimens on the same occasion which reduced all the discussion on the subject of the pad of Alytes to the level of "straining at a gnat and swallowing a camel." For all critics and supporters of Lamarckism alike admit that Alytes is descended from ancestors which, like more normal toads, possessed pads, and that the appearance of a pad in Alytes is therefore an atavism.

The most wonderful experiment, however, which Kammerer has ever published was that in which, *in one generation*, he had induced the blind cave-newt Proteus to develop a fully-formed eye. These creatures he brought with him to England, and there was no possibility of mistake about the matter. Proteus cannot be confounded with anything else; its pale flesh colour and reduced limbs are characteristic, and newts of this kind with large well-formed eyes were shown at the discussion. One is inclined to ask whether it is easier to produce a fully-formed eye than a mere cornification of the skin.

Kammerer's results have in the meantime been confirmed by the independent work of Durkhen on the colour of the pupæ of white butterflies. This work was carried out in the University of Breslau, and was published in 1923. The pupæ of this species normally have an opaque skin of a greyish-white colour, but in a small percentage (about 4 per cent.) this colour is absent and the skin is transparent, and so the pupa appears green, owing to the green blood shining through. If, however, the caterpillars are exposed to orange light, the formation of the white pigment of the pupa is largely inhibited, and the proportion of green pupæ rises to 65 per cent. If these pupæ are allowed to develop into adults and produce offspring and the caterpillars of the second generation are exposed to the same conditions, then the proportion of green pupæ rises to 95 per cent.; if the caterpillars of this generation are, however, left in ordinary daylight, the proportion of green pupæ diminishes, but is still 34 per cent. as compared with 4 per cent. in the controls. Here, as in Kammerer's experiments, we see that the reaction to the environment on the part of the first generation affects the second generation, and that a trace of it persists even when the second generation is replaced in the original conditions.

In England, Dr. Heslop Harrison, of the University of Durham, has observed that a certain melanic variety of moth is found where the food plants are infected with manganese salts derived from the smoke of adjacent factories. He fed the pale variety of this moth on food impregnated with the salts of manganese, and after several generations succeeded in obtaining melanic specimens, and from these he obtained a melanic progeny which bred true.

We are, therefore, in a position to state that after the lapse of the first quarter of the twentieth century, the doctrine of Lamarck has been submitted to the crucial test of experiment and proved to be true. Now evidence of the actual course of evolution is derived from three classes of facts, namely, those of systematic zoology (*i.e.* the mutual relations of varieties and species), those derived from a study of embryology, and, finally, those deduced from palæontology or the study of fossils, and systematists, palæontologists, and embryologists alike have been forced to the conclusion that the effects of habits must be inherited in order to account for the facts which they find in Nature. We are therefore justified in saying that habit, which is the reaction of the animal to its environment, has been the great factor in evolution, and that the splitting of the original stock into divergent species has been due to different members of the same stock under the stress of different environments adopting different habits. Prof. McDougall in "Psychology" has shown that this readiness to adopt new habits is a universal characteristic of living beings. "An animal when its activity is roused by a stimulus," writes McDougall, "pursues an end, and its activity continues till that end is attained or until it is exhausted. If it fails to attain that end in one way, *it will endeavour to gain it in another* until it achieves success." In this sentence, we venture to think, is contained the key to the riddle of evolution.

We might leave the subject here, but considering the vogue that the mutation theory of evolution has had, it is proper to consider whether any definite cause for these mutations can be found, and if so, what relation this cause bears to the reactions which set up habits.

Nothing has been more remarkable than the consensus of opinion of the upholders of the mutation theory that mutations are due to "chance," and yet, as Huxley remarked, one had hoped that a belief in chance had been finally exploded Quite recently, however, a physiological cause for mutations has been suggested by Tornier, and much evidence in favour of it has been collected by him. The special subject of his investigations was the goldfish The most bizarre races of this creature have appeared, and these races when crossed produce offspring which obey the Mendelian rules. Now Tornier showed that the races of goldfish had been derived from a small species of carp which inhabits the rivers of China. He found that the Chinese breeders kept their stock in small dark jars under insanitary conditions in which they were scantily supplied with oxygen Much of the spawn died, and among the survivors all sorts of abnormalities turned up; from these the most striking specimens were selected and used to found the new breeds These facts suggested to Tornier the view that the cause of the mutations was the weakening of the developmental energy of the germ by the abstraction of oxygen during an early and critical period of development

Tornier showed that this weakening had two consequences: (1) it made the embryo sluggish in its movements, and (2) it diminished its power of regulation of the various processes on the harmonious co-operation of which the upbuilding of the body depends. Thus enormous fins were produced by the swelling of the yolk in consequence of undue absorption of water underneath the skin-area from which the fin developed, telescopic protruding eyes by the engorgement of the growing eyeball with water, and so on. By treating the eggs of newts and toads in such a way as partly to suffocate them for a short period after fertilisation, similar embryos were produced. Independently of Tornier, Jansen had arrived at a similar explanation of the cause of human deformities, the part played by the pressure of the swollen yolk in the goldfish's egg being assumed in the human embryo by the pressure of a too closely adherent amnion. What is inherited is, according to Tornier, not a factor or gene for an enlarged fin or protruding eye, etc., *but a certain grade of germ-weakness which in each succeeding generation produces the same morphological effects*

If this view is correct—and all the evidence available conspires to show that it is—then mutations can have played no part whatever in evolution Since they are the outward and visible signs of a weakened constitution, they are in a state of Nature ruthlessly weeded out by natural selection. Nevertheless they, like functional adaptations, are the result of the action of the environment—only in their case the animal has *failed to respond* to the changed conditions, whereas evolution depends on cases where the animal *has successfully responded*. In the last resort, therefore, like Darwin we come back to natural selection, only what is "selected" is not a chance variation or peculiarity but the constitutionally vigorous individual with ability of self-adaptation; what is rejected is the individual of weakened constitution.

Obituary.

SIR WILLIAM E. GARSTIN, G.C.M.G., G.B.E.

SIR WILLIAM GARSTIN, whose death at the age of seventy-five occurred on January 8, commenced his career in India in 1872 as an officer of the Public Works Department, after studying engineering at King's College, London Thirteen years later he was invited by Sir Colin Scott Moncrieff, who had just taken charge of the Public Works Ministry in Egypt, to make one of the small group of Indian engineers who were undertaking the reorganisation of the irrigation system of Egypt, which was at that time in complete disorder

In charge of the Circle of Irrigation which included the eastern half of the Nile Delta, Garstin spent seven arduous years in effecting his share of the restoration of the irrigation system, and then, on the retirement of Col Justin Ross in 1892, he was appointed Inspector-General of Irrigation for the whole country. A few months later, on the retirement of Sir Colin Scott Moncrieff, he became Under-Secretary of State in the Ministry of Public Works.

At that time the irrigation system was being rapidly improved; the basin irrigation of Upper Egypt had been largely remodelled by Col. Ross, improvements in the Delta had led to large increases of crops, and larger supplies of water in the early summer were urgently required. Plans for a reservoir in or near the Nile Valley were being studied, and it fell to Sir William Garstin to advise on the scheme to be adopted. As a result, the Aswan Dam with subsidiary barrages at Assiut and Zifta were built, and by these means, and later developments of them, Egypt's low-stage water supply was assured.

As soon as Omdurman had fallen and the Sudan had been retaken, Garstin took prompt measures for the clearing of the Bahr el Jebel and the Bahr el Ghazel from the "sudd"—those blocks of drift and growing vegetation which had closed many of the channels Sir William visited the Sudan on numerous occasions, and especially in 1901, and again in 1903, when he traversed Uganda also to see the headwaters of the Nile system. The investigations and surveys which were then initiated have since furnished a mass of hydrographical information of the highest value both to Egypt and to the Sudan.

Although his work in relation to irrigation is the most known in Great Britain, Garstin's position as the senior officer of the Ministry of Public Works in Egypt brought him in contact with many other forms of the public service. On his recommendation a geological reconnaissance of Egyptian territory was started in 1896, which soon developed into the present Geological Survey. The Survey of Egypt commenced in the Ministry of Public Works while he was in charge, and

he warmly supported the various scientific activities which grew up in connexion with it.

The Department of Antiquities has always formed a part of the same Ministry, and in its work and its responsibilities Garstin always took a keen interest. As soon as the Aswan Dam was decided upon, entailing the partial submergence of the island and temples of Philæ, he took measures for the complete underpinning of all parts of the buildings which were not founded on rock; and later, when the raising of the Dam became necessary, he obtained the allocation of a considerable sum for the execution of an archæological survey of that portion of the Nile Valley which would be submerged. The present Museum at Cairo is also due to his efforts to house safely the ever-increasing collections of Egypt's ancient civilisation

A keen sportsman, the wild fauna of the Sudan strongly attracted Sir William Garstin, from its inception he strongly supported and took an active interest in the Zoological Gardens at Giza

H. G. L.

We are indebted to *Science* of November 28 for the following details of the life and work of Prof. W. A. Locy, professor of zoology in Northwestern University, Illinois, who died on October 9 at the age of sixty-seven. William Albert Locy was born at Troy, Michigan, of Dutch ancestry, and received his early training in the University of Michigan. During the year 1884–85 he held a fellowship at Harvard, where he completed an embryological investigation on "The Development of *Agelena nævia*." In 1887 he went as professor of biology to Lake Forest University, where he remained nine years. During this period he published important papers on the embryonic development of the elasmobranchs, the derivation of the pineal eye, and the structure and development of the vertebrate head. In 1896 Locy succeeded Prof. E. G. Conklin at Northwestern University, where he remained until his death. His work there had two aspects, one, the developmental history of the sense organs, to some extent a continuation of his earlier researches; the other, the history of biological science. In 1908 he published a collection of historical portraits entitled "Biology and its Makers," which has since been translated into German, while in 1918 he produced "Main Currents in Zoology," and at the time of his death he was completing another work, "The Rise of Biology." The significance of his work on the history of science was recognised by his election as the first president of the History of Science Section of the American Association. He was also president in 1915 of the American Society of Zoologists.

We regret to record the death, at the age of sixty-seven, of Prof. J. Bergonié, professor at the clinic for medical electricity and biological physics in the University of Bordeaux. Prof. Bergonié was chiefly known for his work on electro-therapy. He was the author of numerous papers, and was for many years editor of the *Archives d'Électricité médicale*, in which journal most of his original publications appeared. Among the most important of his original contributions to medicine we may mention "Contributions à l'étude du phénomène physique du muscle" and "Physique du physiologiste et de l'étudiant en médecine" (1892). Prof. Bergonié invented an ingenious device for localising metallic foreign bodies in the human subject, which was used to some extent in the War. He also invented an apparatus designed to treat the condition of obesity. He died as a result of injuries associated with X-rays and radium. During the last few years he had been actively at work upon the anti-cancer centre at the Hôpital St. André, Bordeaux. He twice received the gold medal of the Carnegie Foundation.

In the issue of the *Physikalische Zeitschrift* for November 15, Prof. E. Warburg gives a sympathetic account of the life and scientific work of his former assistant and colleague, Karl Richard von Koch, who died a short time ago after having resigned the professorship of physics at the Stuttgart Technical School in 1919 owing to heart trouble. Prof. Koch was born at Stettin in 1852, and after studying at Bonn, Freiburg and Gottingen, graduated Ph.D. at Freiburg in 1875. While librarian there he commenced research in physics under Warburg, and was appointed lecturer in physics in 1881 and extra professor in 1886. In 1888 he became professor at the Aachen, and in 1891 at the Stuttgart Technical School. Here he designed the new Physical Institute, opened in 1910, which has since served as a model of what such an institute should be. His scientific work lay mainly in the direction of improving methods of measurement, especially in elasticity, but he took great interest in the application of physical principles to practical problems and to natural phenomena. His best-known researches are probably those on the elasticity of metals at high temperatures, on the determination of gravity, and on the auroræ.

We regret to announce the following deaths:

Prof. S. A. Beach, professor of agriculture at Iowa State College, who was known for his work on apple growing and whose name is included in the list of honorary and corresponding members of the Royal Horticultural Society, on November 2, aged sixty-four.

Mr. Alfred H. Brooks, for twenty years chief of the Alaskan Division of the United States Geological Survey, on November 21, aged fifty-three.

Dr. E. Hedinger, professor of pathological anatomy and histology in the University of Zurich, and formerly of the University of Basle, who, in 1914, undertook a special mission to South Africa to investigate trypanosomiasis in cattle, on December 24, aged forty-eight.

Dr. Theodore Hough, dean of the medical department and for seventeen years professor of physiology in the University of Virginia, who worked on the factors regulating breathing and on related subjects, aged fifty-nine.

Mr. A. H. Savage Landor, well known as a traveller and explorer in Tibet and China and also in South America, on December 26.

Mr. F. G. Newton, director of the Egypt Exploration Society's excavations in Egypt, on December 25, aged forty-six.

Dr. B. R. G. Russell, of the Imperial Cancer Research Fund, who made noteworthy contributions to our knowledge of tumour transplantation and of the respiration and carbohydrate metabolism of normal and cancerous tissue, on December 22, aged forty-four.

Current Topics and Events.

In the *Times* of November 14 a special correspondent in Berlin, dealing with the disarmament of Germany, stated that the German intention "to increase the frightfulness of war by new methods" was finding "its expression in the creation of a great laboratory attached to the Kaiser Wilhelm Institute near Berlin, the object of which is to study war from the scientific point of view" "This mysterious, powerfully equipped, and strongly financed laboratory," it was added, "works in close contact with several parallel institutions scattered over Germany, and especially with the Gas Testing Institute in Hanover" This allegation has been met by a letter from Dr H Freundlich, the Deputy Director of the Kaiser Wilhelm Institute, refused, he states, by the *Times*, and so published in the *Berliner Tageblatt* of December 16 Dr Freundlich states, in the most explicit terms, that neither in the Kaiser Wilhelm Institute for Physical Chemistry and Electrochemistry, nor in any other Institute associated with the Kaiser Wilhelm Society, is there any work in progress that has the purpose of developing war from the scientific point of view, and that all work there undertaken is exclusively scientific and technical investigation for the industries of peace, and having nothing to do with the purposes of war. Finally, Dr Freundlich invites the correspondent of the *Times*, accompanied by any expert he may choose, to visit the Kaiser Wilhelm Institute, so that he may investigate fully the situation and the character and purpose of the work which is being there carried out. We cannot, of course, know the considerations which led the *Times* to decline to publish this very emphatic repudiation of a serious charge, yet it seems highly desirable that the invitation of the Deputy Director of the Institute should be accepted, and the results made known in Great Britain. What can be credited to our late enemies should be credited, and if there could be an assurance that the great Institute, which was, and is still, presided over by Dr Haber, is now entirely detached from scientific work relating to warfare, it would be welcome news to all who are waiting for additional signs of a real regeneration of Germany in heart as well as in economic prosperity

It is unfortunate that the mere mention of the word atom in a scientific lecture to which reporters are admitted now usually leads to sensational statements in the daily press, much to the annoyance of the lecturer and the detriment of scientific truth. This happened last week in connexion with a lecture delivered at the University of Leeds by Prof R Whiddington during a meeting of the Science Masters' Association The lecture consisted merely of a general account of the present position of atomic physics with special reference to the work of Rutherford and Bohr Prof Whiddington's allusions to his own work were made to indicate the lines along which investigation into X-ray electrons and vacuum discharges was being attempted in the University of Leeds, and to give those members of the audience who so wished, an opportunity of seeing the kind of apparatus used It is scarcely necessary to say that no extravagant claims of the kind suggested in a London newspaper were put forward by Prof. Whiddington or implied in what he said, and the most charitable explanation of the fantastic account published is that the reporter could not sufficiently well comprehend a lecture delivered to an audience consisting mainly of university graduates in science

The following presidents and recorders have been appointed for the meeting of the British Association to be held at Southampton on August 26-September 2: *Section A* (Mathematics and Physics)—President: Dr G C. Simpson, Recorder Prof A M Tyndall, University, Bristol. *Section B* (Chemistry)—President Prof C H Desch; Recorder: Dr H McCombie, King's College, Cambridge *Section C* (Geology)—President. Dr. W G Miller, Recorder: Prof. W. T Gordon, King's College, Strand, W.C.2. *Section D* (Zoology)—President: Mr. C Tate Regan; Recorder Mr. F Balfour Browne, Dysart House, Luard Rd, Cambridge *Section E* (Geography)—President: Mr A R Hinks, Recorder. Dr R N Rudmose Brown, University, Sheffield *Section F* (Economic Science and Statistics)—President (not yet appointed), Recorder. Prof H. M. Hallsworth. *Section G* (Engineering)—President: Sir Archibald Denny, Bart., Recorder: Prof. F. C Lea, University, Sheffield. *Section H* (Anthropology)—President: Dr. T Ashby, Recorder: Prof H J Fleure, University College, Aberystwyth *Section I* (Physiology)—President. Prof A. V. Hill; Recorder: Dr. J. H. Burn, Felden Close, Boxmoor. *Section J* (Psychology)—President: Prof C Spearman; Recorder: Dr Ll Wynn Jones, 7 St Mary's Avenue, Harrogate. *Section K* (Botany)—President: Prof. J. Lloyd Williams, Recorder: Mr. F T Brooks, 31 Tenison Avenue, Cambridge. *Section L* (Educational Science)—President: Dr. W. W. Vaughan, Recorder: Mr C. E. Browne, Christ's Hospital, West Horsham. *Section M* (Agriculture)—President. Dr. J. B. Orr; Recorder Mr. C. G T. Morison, School of Rural Economy, Oxford.

Of the many recent efforts made by British manufacturers to establish a home industry in the production of colouring matters, one of the most successful has been the enterprise started under the wise inspiration of Mr. James Morton, of the Morton Sundour Fabrics, Ltd., of Carlisle. Until 1914, this firm was entirely a dye-using undertaking dependent on continental sources for its supply of fast dyes The stoppage of German supplies of colours consequent on the outbreak of war led Mr. Morton to turn his attention to the production of these essential dyestuffs, and, gathering together a group of chemists, he encouraged them to work out the difficult problem attendant on the large-scale production of modern vat colours, a group of chemical substances having highly complicated constitutions. By the end of 1915, the intricacies of indanthrene blue and flavanthrene (indanthrene yellow) had been unravelled,

and these colours were being turned out on a manufacturing scale. Other dyes of the same class speedily followed. These persevering investigations were not, however, restricted to the imitation of foreign products. The chemists of the Sundour factory, with commendable initiative, extended the scope of their work to the search for entirely new colouring matters. Here again they achieved a noteworthy success in the discovery of a new group of dyes, known as the Caledon Jade-green series, for the typical representative of this group is unsurpassed for fastness and colouring power

A FURTHER important development is now announced from Scottish Dyes, Ltd., an offshoot of the Sundour firm. Processes have been discovered for rendering soluble the anthraquinone vat colours, in this way overcoming one of the disadvantages attending the use of these insoluble dyes. The process is being applied particularly to Caledon Jade-green, and the improved product is known as Soledon Jade-green. Similar soluble colouring matters can be obtained from other vat dyes of the anthraquinone series and render it possible to apply these colours to cotton and wool equally. In the case of the latter textile, this application will lead to a marked increase in the fastness of dyed woollen fabrics. The above-mentioned developments taken in conjunction with the industrial success which has crowned the recent investigations of chemists in other British colour factories demonstrate conclusively that scientific research is not merely a necessary but a profitable form of expenditure in all commercial undertakings dealing with chemical products.

AMONG the activities of the League of Nations, which celebrated its fifth anniversary on Saturday, January 10, are several of particular interest to workers in pure and applied science. The Transit Organisation of the League is engaged in work on matters concerning road traffic, inland and maritime navigation, telegraph, telephone and wireless facilities, calendar reform, etc. In the past year the Health Organisation has, in the words of the Fifth Assembly, "extended its sphere of action, improved, completed and defined its technical equipment, and is thus carrying out with increasing success its special task, which is to give effective help to the various national administrations in their campaign against epidemics and their attempts to improve public health." The Committee on Intellectual Co-operation, to which Prof. Einstein has returned, and M. Lugones, a distinguished Argentine *savant*, has been added, is organising and developing its work on bibliography, exchange of publications, inter-university relations, and the pooling and distribution of scientific information. This Committee held an extraordinary session in Paris on Monday, January 12, under the presidency of M. Henri Bergson (France). Prof. Gilbert Murray represented Great Britain, and other members of the Committee include Prof. Einstein (Germany), Mme. Curie (Poland), M. Jules Destrée (Belgium), Sir J. C. Bose (India), and Prof. R. A. Millikan (U.S.A.). The principal item on the agenda was the question of the organisation of the International Institute for Intellectual Co-operation, which was recently offered to the League by the French Government. The proposed Institute, which is to be established in Paris, will be under the direction of the International League Committee in Geneva, and it will be the duty of this Committee to draw up such rules and regulations for its organisation as will safeguard the international character of the Institute.

THE British Broadcasting Company's new high-power station 5XX is being constructed at Daventry, Northamptonshire. The site of the new station is in open country, about 600 feet above sea level, and 400 feet higher than the surrounding land. A "T" aerial will be used, and an 800-foot and a 500-foot mast are being erected, the transmitter being situated directly under the centre. The antenna has been designed so that its natural wave-length should be about 1600 metres, which is to be the wave-length used for transmission. The power rating is nominally 25 kilowatts, but the actual power used at the station will be 100 kilowatts. The earth system consists of a circular metal plate laid underground and has a radius of 100 feet. It will be connected with the London studio 2LO by means of an overhead telephone line, but an emergency underground cable will also be installed. It is expected that good crystal reception will be obtained up to a radius of about 100 miles. Transmissions will take place in the afternoon and evening. Special programmes of its own will be provided two days of the week, a relayed provincial programme on a third day, and relays of the London programme for the remainder of the week. The first programme will take place in a few months' time.

IT is evident that the visit of the Parliamentary Commission to East Africa, referred to in our leading article of January 10, has had some effect in directing the attention of the colonial governments to the cause of scientific research. By a happy coincidence, while Major A. G. Church was making a plea for greater encouragement for scientific institutions at the St. Andrew's Dinner at Mombasa, the Governor of Kenya Colony, Sir Robert Coryndon, at the corresponding function in the capital, made the same appeal and made use of the same illustration, namely, the Amani Institute. He stated that Kenya Colony is much behind the times so far as scientific research is concerned, and particularly in the investigation of human and animal disease, in botany and in ethnology, and there is lack of co-ordination amongst the East African Colonies on such questions. Sir Robert said that scientific workers in Kenya are too few, that they are working under very difficult conditions, and he would welcome the establishment of a central laboratory in which scientific problems could be properly attacked. Regarding the Amani Institute of Tanganyika, he deplored the fact that nothing has been done since the War to develop the work begun by the Germans, and upon which many thousands of pounds was spent by them. In paying

a tribute to the work of Dr van Someren, who was responsible for the building and the collections of the Natural History Museum of Nairobi, the Governor made an appeal for the support of public-spirited men for the upkeep and improvement of that institution, laying stress on the fact that the cultural aspects of life must play an increasingly important part in the affairs of Kenya Colony

A PARTY of 32 undergraduates from the Engineering Departments of the University of Cape Town are at present on a tour in England Accompanied by eight members of the staff, including Profs Bohle, Plant, McMillan, Snape, and Boyd, they arrived in London on December 31, and their stay will extend over five or six weeks The objects of the tour are to bring the students into close touch with British manufacturers and to give them a broader outlook on life in general. The whole trip has to be completed within the long summer vacation The first fortnight has been spent in the London district, where, in addition to visiting the historic buildings, special visits have been made to the National Physical Laboratory, Science Museum, Woolwich Arsenal, and to some important firms From London the party proceeds to Birmingham, Manchester, Preston, Liverpool, Newcastle, and Sheffield Each student has to submit a report of the tour which, if the professor of mechanical engineering considers satisfactory, will count in lieu of the six weeks' vacation workshop course usually taken in the summer Many of the students from Cape Town after finishing their four years' course come to England for experience in works, and remain here While there are a fair number of openings for civil engineers in the Public Works and Irrigation Department of the Union Government it is more difficult for electrical and mechanical engineers to find employment in the colony. In organising this unique tour, the Dean of the Faculty of Engineering, Prof H Bohle, has been assisted by the staff of the High Commissioner of the Union of South Africa and the officials of the Union Castle Mail Steamship Company, and as a result it has been possible to carry out the complete trip, lasting twelve weeks, for 65*l.* a head.

THE disappearance of seals of economic value from their more accessible breeding-places, under the pressure of the seal-hunter, has intensified their destruction in more remote areas From some of these they have already been exterminated — the fur-seals (*Arctocephalus australis*) and sea-elephants (*Macrorhinus leoninus*) of Gough Island have all but gone—and there is a danger that in their other southern haunts such seals and the less valuable Weddell, crab-eating, and Ross's seals of the Antarctic circle may ultimately be reduced to the vanishing point We therefore welcome the announcement (*Times*, January 6) that the French Government has decided to create a preserve for seals and for penguins, which are destroyed wholesale in some areas for their feathers and oil, on the territories belonging to France in the Southern Ocean. These include Kerguelen, the Crozet Archipelago, St. Paul and Amsterdam islands, and the Adélie Land sector of the Antarctic continent. In these areas the destruction of seals and penguins will henceforth be illegal The crux of the efficacy of animal sanctuaries, however, lies in the proper enforcement of the law, and we doubt whether the policing of these widely scattered scheduled areas by naval patrols based on Madagascar, as is proposed, will be so thorough as one could wish to see

EVERY one familiar with astronomical and other optical instruments will see with regret the announcement that the old-established firm of Sir Howard Grubb and Sons, Ltd, St Albans, and formerly of Dublin, has gone into voluntary liquidation, and is for sale The business was founded in Dublin early in the nineteenth century by Sir Howard Grubb's father, the late Mr Thomas Grubb, F R S, who was engineer to the Bank of Ireland and designed and constructed the machinery for the manufacture of the bank notes. Although made seventy or eighty years ago, this machinery was still in use four or five years ago and probably is so still A number of machine tools, such as lathes, planing, engraving, wheelcutting and dividing machines, were made by the firm, as well as many portrait lenses The works were moved from Dublin to St Albans in 1918 in connexion with the manufacture of periscopes for British submarines Among the important astronomical instruments made by the firm are the following. 27-inch refractor and dome for Vienna, 26-inch photographic refractor for Greenwich, 24-inch photographic refractor with 18-inch guiding telescope for Cape Town, and a similar instrument for the Radcliffe Observatory, Oxford, with dome and rising floor; 26-inch refractor for Johannesburg, mounting for 24-inch refractor for Santiago, Chile, 40-inch reflector for Simeis, Crimea, 7-metre solar spectrograph for Pulkovo, the 13-inch photo telescopes with 10-inch guiders for the International Photographic Survey of the heavens, erected at Greenwich, Oxford, Dublin, Cork, Capetown, Mississippi, Melbourne, Tacubaya (Mexico), Perth (W.A), etc. It is greatly to be deplored that a firm with such a record of splendid work, and a reputation so high among optical instrument manufacturers, should have lacked sufficient support to keep it in existence as a profitable concern.

THE late Prof. John Milne, the distinguished seismologist, was among those commemorated a few days ago in a ceremony at Tokyo in honour of living and dead foreign benefactors of Japan.

A SERIES of six Hunterian lectures on "Recent Discoveries of Fossil Man" will be delivered by Sir Arthur Keith at the Royal College of Surgeons of England on January 19, 21, 23, 26, 28, and 30, at 5 o'clock each day.

THE Council of the Geological Society has this year made the following awards:—*Wollaston Medal*: Mr G. W. Lamplugh; *Murchison Medal*: Dr. H. H. Thomas; *Lyell Medal*: Mr J. F. N. Green; *Bigsby Medal*: Mr. C. W. Knight; *Wollaston Fund*: Dr. A. Brammall; *Murchison Fund*: Dr. A. E. Trueman; *Lyell Fund*: Dr. J. A. Thomson and Dr. W. A. Richardson.

WITH reference to the note in our issue of January 10, p. 60, on the proposed motor tours across the western Sahara to Timbuctoo, organised by Citroën Cars, Limited, it is announced that as absolute security cannot be relied upon along the Colomb-Bechar—Timbuctoo route, the opening of the service between the two points has been suspended for a period of at least one year.

APPLICATIONS are invited by the Metropolitan Asylums Board for the two following appointments, namely, the directorship of the board's pathological services and that of their diphtheria antitoxin establishment Particulars of the appointments and forms of application can be obtained from the Clerk of the Board, Victoria Embankment, E C 4 The completed forms must be received not later than the morning of Wednesday, January 28

APPLICATIONS are invited for the post of an assistant agricultural chemist for the Division of Research, Lands and Forests Department, Sierra Leone Candidates must hold an honours degree in natural science (chemistry being the principal subject), or associateship of the Institute of Chemistry, and a diploma in agriculture Further particulars and the form of application are obtainable from the Private Secretary (Appointments), Colonial Office, Downing Street, S W.1

MR RICHARD H. BURNE has been awarded the Honorary Medal of the Royal College of Surgeons of England for "services rendered to the advance of biological knowledge." Mr Burne has greatly extended the Department of Comparative Physiological Anatomy in the Museum of the College, of which department he is the Curator The medal thus awarded, although founded in 1802, has been awarded only eleven times previously. The list of former recipients includes the names of Sir Richard Owen, Sir James Paget, Lord Lister, and of Sir R. Havelock Charles.

Our Astronomical Column.

THE SOLAR ECLIPSE OF JANUARY 24.—This eclipse cannot be regarded as of great importance for the study of solar physics, owing to the unfavourable season of the year, and the rather low altitude of the sun at all the land portions of the track of totality The eclipse derives some interest, however, from the populous regions which it traverses in Canada and the N E corner of the United States, including some outlying districts of New York

Efforts have been made to induce the general public to join in the observations; in particular, to note the exact duration of totality at numerous points close to the northern and southern limits This will enable the exact position of the lunar node to be determined, as Newcomb did from similar observations in England in 1715 Numerous observatories lie within the totality track, so that full advantage will be taken of any opportunities for useful work that weather conditions may afford The altitude is too small for study of the Einstein shift, which was, moreover, dealt with sufficiently in 1922

The eclipse has some interest in the British Isles from the fact that, after a barren interval of two centuries, there is a very near approach to totality at St. Kilda in the Western Hebrides The sun's altitude is, however, insufficient for any useful work, and landing on St. Kilda is generally difficult in winter. There is a large eclipse throughout the British Isles, beginning about $14^h\ 45^m$, and greatest phase an hour later. The magnitude reaches 0 94 at Glasgow, 0 82 in London.

It would seem that the only observation of value that can be made in Britain is the careful timing of the first contact. Dr. Innes proposed a useful method of improving the determination by frequent measures of the distance between the cusps for the first minute or so. If the projection method be employed, two observers can mark on the screen the positions of the North and South cusps at prearranged beats of the clock. This method was found practicable at Greenwich in April 1921.

WOLF'S COMETARY OBJECT OF DECEMBER 22.—Observations of this object on December 22, 23, 25, 26 are now to hand. Dr. A Kahrstedt, of Berlin-Dahlem, has deduced the following (still very uncertain) elliptical orbit from the first 3 positions (Copenhagen Circular, No 56)

T	1925 March 27 7308 G M T (new)
ω	219° 32′ 38 0″
Ω	264 47 14 8
i	14 47 11 3
ϕ	40 27 44 4
μ	319 231″
log a	0 69726
Period	11 12 years

The magnitude is estimated as 16 The approach to the sun will probably cause a slight brightening, but the distance from the earth is increasing. The object will remain observable for some months

EPHEMERIS FOR GREENWICH MIDNIGHT.

		R A	N Decl
Jan	14 0	$4^h\ 6^m\ 4^m$	20° 0′
	22 0	4 10 2	18 38
	30 0	4 16 4	17 29
Feb	7 0	4 25 0	16 31

The object is in Taurus, moving towards Aldebaran The elements have some resemblance to those of Faye's Comet, due at perihelion next September Identity, however, does not appear to be possible.

INTERESTING GROUP OF MORNING STARS.—Mr W. F Denning writes "On the morning of Thursday, January 22, the south-eastern sky before sunrise will display the planets Mercury, Venus, and Jupiter, and the crescent of the moon in near companionship. The picture will be a rare and interesting one, but it will not be easy to observe, for the planets involved will rise at about 6 h. 35 m, and this is only 1 h. 20 m. before the sun They will be placed, therefore, very near the horizon, and will require a favourable atmosphere at low altitudes in order to be well seen. If the observer occupies a position commanding a good open view of the south-east, and if weather conditions are good, there should not be much difficulty in detecting the various objects, though twilight will be strong The best time to look for them will be at about 7 A.M. or a little afterwards. Of the planets, Venus will be the most brilliant, Jupiter being next, and Mercury last in the order of magnitude."

Research Items.

ARCHÆOLOGICAL EXPLORATION IN FLORIDA.—Mr. J. Walter Fewkes has been able to take advantage of the commercial exploitation of Weeden Island, Tampa Bay, to explore the shell mounds, which were noted nearly half a century ago as a prominent feature of this part of Florida, but have now to a great extent disappeared owing to the use of their material for road metal. In vol. 76, No. 13, of the Smithsonian Miscellaneous Collections, Mr. Fewkes describes and figures remains found in a preliminary exploration on Weeden Island, which was mainly directed to the investigation of a mound which had been used as a cemetery. The prehistoric aborigines appear to have lived principally on shell fish, but they also ate fish, game, and rodents, and, possibly, roots and fruits. The mound exhibited three layers of stratification, one being modern. In the upper of the two ancient strata, skulls and skeletons occur in numbers, and the implements and a finely decorated pottery point to a relationship with the prehistoric inhabitants of Northern Florida and Southern Georgia. The lowest stratum contains objects belonging to an ancient people of Florida whose origin and affinities are obscure, but whose pottery suggests affinity with the archaic pre-Taínan Ciboney culture of Cuba and the similar early cultures of other West Indian Islands. Whether it was autochthonous in both areas or an extension from one to the other is a question for future investigation.

CLASSIFICATION OF CONSCIOUSNESS.—The presidential address to the Section of Psychiatry, Royal Society of Medicine, delivered by Dr. C. S. Myers, has been printed in the *Lancet* of November 29. Dr. Myers puts forward certain views and aspects, derived from a study of pure psychology, in the hope that they may prove interesting and suggestive to those working in the applied field of medical psychology. He reviews some of the more fundamental problems of psychology, which have of recent years been less frequently considered than before the War, owing to the urgency of more practical problems. Nevertheless it is wise at intervals to view the more abstract problems. Dr. Myers considers the conception of consciousness and discusses the difficulties involved in the usual classification into the three modes, namely, the cognitive, conative, and affective, and offers an alternative scheme. He then outlines the part played by consciousness and shows that its function is to select both from alternative responses and alternative stimuli so as to maintain an environment—whether physical or mental—that shall be favourable, and to avoid one that is unfavourable. For this to be possible, it is necessary that relatively small variations in the environment should differ in the reactions evoked. He shows how the vague complex precedes the differentiated simple and the part played by the power of projection, *i.e.* the ability of the self to regard its own change of states as something outside itself. The reflex act is interpreted not as an original type out of which more complex forms of activity have evolved, but as a decadent form of mental activity. Dr. Myers concludes with a discussion of the relation of consciousness to the brain, and points out that the recent developments of physical science have rendered the difference between mind and matter a different problem from what it was a hundred years ago.

THE BIOGENETIC LAW AND THE GYMNOSPERMS.—The very characteristic and stimulating paper that Prof. E. C. Jeffrey of Harvard read before Section K of the British Association at Toronto, and at Edmonton, is printed in *Science* (vol. 60, No. 1563, December 12, 1924), and will certainly arouse interest amongst European botanists, possibly provoking the retort courteous, from the European view-points so vigorously assailed. To Prof. Jeffrey, the higher plants provide excellent examples of the validity of the doctrine of recapitulation, their witness being free from the obscurities introduced by "larval forms." He cites particularly the normal leaf form to be found in seedling stages of xerophytic Cacti, Veronicas, etc., as also the typical leaves on seedlings of plants later armed only with phyllodes or phylloclades, and the prevalence of the typical evergreen needle upon the seedling conifer, although later these plants may be deciduous, as on larch, or bear leaves confluent with the surface of the stem, as on the arbor vitæ. Prof. Jeffrey then proceeds to discuss the anatomy of living and fossil forms amongst Gymnosperms, and thus finds evidence for three "working principles," namely, (1) recapitulation, (2) the doctrine of retention (instanced by conservative organs, namely, root and reproductive axis); (3) the doctrine of reversion as a result of injury. In analysing the anatomical and fossil data along these lines, Prof. Jeffrey fights over again the phyletic battle of Araucarian phylum versus Abietinean as competitors for ancient standing amongst Gymnosperms, and concludes once more that "when the dust of conflict has settled, it will probably appear that Ginkgo and Pinus stand side by side as the prototypes of Mesozoic gymnosperms of Cordaitean derivation. It will then be realised that Agathis and Araucaria are aberrant extremes, which merely simulate Cordaites on the basis of extremes meeting but have no near affinity with them."

THE COOLING OF THE EARTH.—In the Journal of the Washington Academy of Sciences for December 4, 1924, Leason H. Adams, of the U.S. Geophysical Laboratory, presents a very welcome discussion of the distribution of temperature at moderate depths within the earth. He adopts the method initiated by Holmes in 1915 of utilising the age of the earth as a known factor in the problem. This makes it possible to determine the relative importance of the heat generated by radioactive disintegration, and thus to calculate the internal temperatures from an assumed initial molten state. Cooling at first is controlled almost entirely by convection giving a thermal gradient of nearly 1° C. per km. Convection is gradually terminated either by crystallisation, leading to a gradient of 2.5° to 5° per km., or by increasing viscosity, leading to a gradient less easily calculable, but lying within the range 1° to 10° per km. As a probable average, 4° per km. is adopted for the final computations. These are based on the assumption that below the outer 100 km. the material produced by crystallisation-differentiation would be peridotite, a diabasic zone forming above, and finally a granitic layer. The important principle is then established that on account of the great age of the earth (1600 million years), the temperatures at depths greater than 100 km. are unaffected by any reasonable variation of the initial temperatures in the upper 100 km. For the purpose of calculation, an initial surface temperature of 1200° C. has commonly been adopted (*e.g.* by Holmes and Jeffreys), and it has been argued that, as the surface was probably of granitic composition, a much lower initial temperature would more accurately fit the conditions. However, as the present temperatures depend on the original temperatures at considerable

depths, it is easily seen that 1200° C., far from being too high, is more probably too low. The author takes 1400° C., the melting-point of peridotite, as the effective initial temperature, and gives a temperature curve down to 300 km., which is the best representation of the probable average thermal conditions under the continents yet available.

THE PHOTOELECTRIC PRIMARY CURRENT IN CRYSTALS.—A paper by Messrs. B. Gudden and R. Pohl, in the *Zeitschrift für Physik*, December 6, deals mainly with the positive portion of the photoelectric primary current which is produced by the action of light of long wave-lengths, or thermal molecular movements, on a crystal in which light of short wave-length has caused a flow of electrons to the anode, leaving the positive ions in their original positions in the lattice. The effect has been studied in diamond, with light of a number of different wave-lengths produced by a monochromator, and it appears that wave-lengths of 630-660 $m\mu$ are most effective in producing it. The optical absorption of diamond extends farther towards the red, when the disturbances in the lattice are increased by the positive charges which remain fixed in the lattice after the negative portion of the photoelectric primary current has passed. The authors formerly regarded the primary current as being wholly due to this flow of electrons to the anode; but they now include the positive portion of the current in this term. With blue light, for example, it is shown that part of the primary current is due to the flow of electrons, without inertia, and part to a shifting, step by step, of the resulting positive charges towards the cathode, due to thermal molecular movements. These facilitate the passage of an electron from a neutral atom to the positive ion standing next to it on the side towards the anode. It is probable that, so far as the conductivity mechanism is concerned, the photoelectric phenomenon can be dealt with in the same manner, not only in other crystals in the author's first group, with refractive indices more than two, but also in second group crystals, such as sodium chloride which has been treated with X-rays.

MAGNETISM OF THE COILS OF MOVING COIL GALVANOMETERS.—It has been known for many years that the magnetic properties of the materials used for the suspended systems of moving coil galvanometers have much to do with the troublesome "zero shift" which often greatly increases the labour of the observer. The British Scientific Instrument Research Association (26 Russell Square, London, W.C. 1) has, therefore, done good work in publishing a careful investigation (price 6*s.*) on this subject by Mr. G. Williamson. The author finds that zero shifts can be divided into two kinds: first, those due to temperature changes and, secondly, those following upon deflexions of the coil. The first cause is due to variations in the elastic constants of the suspended strips. The second cause is due to the permanent magnetism of the constituents of the coil. The author makes an exhaustive study of this second cause. He uses two methods of obtaining rough comparative estimates of the permanent magnetic properties of similar specimens. In the first method, he magnetises the specimen by a known strong field and then measures the couple exerted on it by a weaker field perpendicular to the direction of magnetisation. In the second method, he measures the zero shift of the specimen following on a deflexion in a known constant field. He finds that all the materials forming the galvanometer coil—silver wire, wooden former, silk insulation, the mirror itself—showed permanent magnetism. Of the resultant effect, 18 per cent. was due to the wooden former, 33 per cent. to the silk insulation, and the remaining 49 per cent. was due to the silver wire, mirror, binding wires, etc. Some of the effects due to the silver wire could be minimised by heating it in concentrated hydrochloric acid, and the ferro-magnetic effects due to the wooden formers could be diminished by exposing them to hydrochloric acid gas. The silk insulation was much the most difficult to deal with. It was found that the ratio of zero shift to sensitivity diminishes as the magnetic field (*i.e.* the sensitivity) increases.

BEESWAX.—The production, properties and uses of beeswax are described in the *Chemical Trade Journal* for December 12, 1924. Beeswax is formed voluntarily by the bees loading their stomachs with honey and then resting in clusters perfectly still for twenty-four hours. Owing to the introduction of artificial honeycombs in bee culture, European countries have failed to cope with the modern demand, and large quantities of wax are imported from Africa, the West Indies, and Portugal. The imported material is mostly produced by wild bees and is inferior to the product obtained from the home-cultivated bee. The wax is often bleached by exposure to the sun or ozone (extensively used at Leningrad) or by other oxidising agents. The principal constituents are myricyl palmitate and cerotic acid; smaller quantities of myricyl and ceryl alcohols, psyllostearyl alcohol, melissic acid, many hydrocarbons (*e.g.* heptacosane hentreacontane) and unsaturated acids are also present. The physical properties are described in detail, a table of constants being given.

SYNTHETIC SWEETENING COMPOUNDS.—The chemistry of synthetic sweetening compounds is reviewed by G. M. Dyson in the *Chemical Age* for December 6, 1924. The recent researches of Cohn and Holleman are described. The introduction of halogen and other groups into saccharin has the following general effects. The sweetness increases with decreasing molecular weight of the entering halogen group, though nearly all halogen derivatives have a bitter after-taste. 6-Chlorosaccharin is more than half as sweet as saccharin itself, and is sweeter than the 4- and 5-chloro-derivatives. Whereas 4-amino-saccharin is sweeter than saccharin, 4-nitrosaccharin is bitter. The introduction of alkyl groups has little or no effect, though the after-taste is modified. Multiplication of sweetening groups is not always associated with an increase of sweet taste. Sternberg has pointed out that for an aliphatic compound to be sweet, the alkyl groups must not outnumber the hydroxyl groups by more than one; further, the sweetness of an aliphatic compound increases with the number of hydroxyl groups present. Oertly and Lyers have proposed a theory of taste akin to the colour and constitution theory, but the rules are more often broken than followed. Mr. Dyson describes in some detail the preparation of saccharin, and mention is made of "dulcin" and "methyl-dulcin," which are *p*-phenetyl urea and *p*-anisyl urea respectively.

CONDUCTIVITIES OF ELECTROLYTES.—Researches on measuring the conductivities of electrolytes by the induced magnetic field method of Guthrie and Boys have recently been carried out by O. Scarpa (*Gazzetta Chimica Italiana*, November 1924). Adopting this method the author investigates the electrical resistance of, and the influence of a magnetic field on, an electrolyte in motion. The action of a magnetic field on a jet of an electrolyte carrying a current is also described.

The Physical and Optical Societies' Exhibition of Apparatus.

THE fifteenth annual exhibition of apparatus held by the Physical and Optical Societies at the Imperial College of Science and Technology, South Kensington, brought to light a larger number than usual of novel and improved instruments. The standard of workmanship and finish was everywhere high, and it was a pleasure to note that the products of British firms, to which the exhibition was primarily devoted, compare very favourably in these respects as well as in ingenuity and soundness of design with imported goods of a similar character. There was a preponderance of instruments for industrial purposes and for advanced research; a certain number of firms also showed apparatus suitable for educational laboratories, but a greater proportion of apparatus of this type would be welcome at such an exhibition. Special interest also attaches to disassembled instruments; a brass box with knobs is impressive rather than instructive.

In briefly discussing some of the exhibits it is impossible to do justice to most of the stands, which could not be adequately studied in an exhibition lasting only two days. It will be necessary to make an arbitrary selection of apparatus which appeared to be specially interesting on account of its novelty, and to pass over without mention a majority of items the intrinsic importance of which is at least as great.

The most sensational feature of the exhibition was Mr. C. F. Elwell's discourse on "Talking Motion Pictures," illustrated by demonstration films. It must suffice here to remark that no one who saw and heard the demonstration can doubt that the essential problem has been solved, and that for better or worse the talking picture is ripe for commercial exploitation. In addition to other items making for brighter physics, visitors had the piquant experience of being addressed by a very realistic President Coolidge on the American citizen's burden of taxation! An equally interesting discourse and demonstration was given each day by Mr. F. Twyman, who dealt with the Michelson interferometer. In the hands of Mr. Twyman and his assistant, this interferometer became a delicate means for studying temperature distribution in a transparent body: the instrument was so adjusted as to project on the screen a field of substantially uniform colour derived from a source of white light, and on the introduction of the demonstrator's finger into one of the interfering light-beams, lines of colour appeared round the shadow of the finger, these lines representing approximately isothermal contours. Perhaps the most striking of the experiments shown was the "soaking in" of the isothermal lines into a plate of glass when a match had been momentarily applied to the latter, and it was also made possible to "see" petrol vapour poured from a bottle and the lines of strain in glass under stress—the latter application giving effects similar to those which have been obtained by Prof. E. G. Coker with polarised light.

The Cambridge Instrument Company is one of the firms which enters into the spirit of the exhibition and seeks to enhance its interest by the variety of its exhibits and by admirable descriptions given in the programme. The principal *métier* of the firm, the measurement of temperature, was represented by some dial thermometers of the vapour-pressure type, but they were somewhat overshadowed by more intriguing "side-lines." The dial thermometer appears to be displacing the glass thermometer from industry, for Negretti and Zambra also made a feature of thermometers in which a mercury bulb communicates with a dial-control through steel-lined tubing. An interesting improvement in calorimetry is the use of stainless steel in a bomb calorimeter (Griffin). For taking the temperature of buried cables, Siemens measures the resistance of a nickel pilot wire fitted to the latter.

Items of interest to meteorologists included an Assmann psychrometer ventilated by an electrically driven centrifugal fan, shown by Negretti and Zambra. It is to be hoped that this or a similar firm will succeed in solving the hitherto unsolved problem of constructing a self-acting hygrometer with permanent zero; apart from this latter consideration the firm's recording hair hygrometers appear to be fool-proof. A simple and ingenious recording barometer of great sensibility (Hughes) is that designed by S. G. Starling: the mercury bulb is connected to the vertical column of the barometer by a horizontal tube of substantial length, the whole being mounted on a pivoted board hanging in a vertical plane. Movement of the mercury causes the board to tilt, while a pen carried by the board traces a record on a chronometric drum. Short and Mason, by a special design of the linkwork controlling the pen of a barograph, are able to provide the latter with an exceptionally open scale. A novel kind of cloud photograph is taken with the Robin Hill lens (Beck), which has an angle of 180°, so that a photograph of the whole sky can be taken on a single plate. Such a photograph is of value in spite of its distortion, but if necessary a selected section of it can be straightened out by copying with the lens reversed.

Two interesting oscillographs were those shown respectively by Tinsley and Co. and by the Cambridge Instrument Co. The former is of the inertia-less cathode-ray type and employs a hot cathode, high sensibility with low voltage being thus secured. The cathode stream is focussed into a pencil by surrounding the filament with a positively charged sheath. The Cambridge instrument, on the other hand, is an improvement on the Duddell oscillograph and enables simultaneous records to be obtained from three separate vibrators which are replaceable and may be electrostatic or electromagnetic in any combination. Intense illumination is secured by applying a momentary excess voltage to the 4-volt metal filament lamp during and immediately before exposure of the travelling photographic film. The Campbell frequency meter, which aroused much interest when it was recently described before the Physical Society, was also shown by this firm. It depends on a bridge system employing mutual inductances, covers a range of from 200 to 4000 cycles, and attains an accuracy of about 1/10 per cent. Other meters worth noting were a series for various quantities (ammeters, voltmeters, etc.) but uniform exterior by the Weston Electrical Instrument Co. These are of convenient square form but comparable in price with those of less portable design. A very interesting detail of design has been introduced into the Cirscale moving-iron instruments (Record Electrical Co.) in order to secure a pointer movement of 300°. These instruments are of the type in which a pair of soft iron strips inside a solenoid are magnetised by the same field, so that the repulsion between them measures the energising current. In the present instance, two pairs of such strips are used: one member of the first pair is fixed, while the "fixed" member of the second pair is carried round by the moving member of the first pair, the two latter members being rigidly joined together but spaced apart along the axis of the solenoid. The Rayworth's voltmeter (Elliott Bros.) for testing accumulators is provided with a

differential winding and a cadmium electrode so arranged that, in addition to ordinary testing, comparison of the potential of each plate with that of the cadmium electrode can be carried out, and further, the unexpended charge remaining in the cell can be measured. The Darimont electric batteries have the interesting feature that the exciting and depolarising solutions are separated by a semi-permeable membrane created by the reaction which takes place between the solutions themselves

For testing overhead A.C. mains, Crompton and Co. provide a hinged-core transformer. The ring-shaped core is passed over the main and closed so as to surround the latter, which then forms the primary of the transformer, while the winding on the core forms a secondary and enables the current in the main to be tested. Impedance apparatus included the Duwatcon condenser for wireless (Dubilier Condenser Co.), so designed that its range for series connexion slightly overlaps its range for parallel connexion, thus obviating the gap in tuning range which ordinarily occurs when the connexion is changed, and three interesting variometers. Of these the Mansbridge is flat in shape and comprises D-shaped coils: used alone it will cover all the B.B.C. wave-lengths, and in conjunction with a fixed condenser of 0·002 μf will cover wave-lengths up to 1800 metres. A similar range is attained in a variometer by the Marconiphone Co. by means of a series-parallel switch. In the "wound on air" variometers of the Igranic Electric Co. the windings are spherical and entirely self-supported.

Amongst wireless apparatus, the Multivibrator wavemeter designed by D. W. Dye (Sullivan) attracted much attention. In this arrangement a specially constant tuning-fork, maintained in vibration by a thermionic valve, controls by accordance a multivibrator comprising two valves so cross-coupled as to generate oscillations rich in harmonics at approximately the same fundamental frequency as the fork. By selective amplification, harmonics up to the 120th can be picked out and heterodyned with the oscillation the frequency of which is to be measured, and by using two such arrangements in series a harmonic of frequency $1{\cdot}2 \times 10^6$ can be utilised. A complete "public address system" for amplifying speech or gramophone reproductions was shown in action by Marconi's W. T. Co., high-power water-cooled valves as used for broadcast transmission by the M.O. Valve Co., and the newest types of dull-emitter and other valves by the latter, the Mullard Radio Valve Co., and Cossor. A fool-proof emergency wireless transmitter for ships' lifeboats was shown by Evershed and Vignoles.

As regards line telegraphy, it was gratifying to notice a column printer of British manufacture (Creed and Co.). Morse line currents are converted to printed matter arranged in columns like that given by an ordinary typewriter, as in the American instruments which have hitherto held the field. The direct-working sounder of the India Rubber, etc. Works Co. introduces the long overdue reform of replacing the pony sounder by a far more efficient device employing a diaphragm.

A radium clock has been devised by Mr. Harrison Glew the radium for which may be that contained in an ordinary applicator or other container which can be removed from the clock when desired: in fact, the period of the clock may be used as a measure of the quantity of radium in any vessel to which it is connected. An interesting high-voltage high-resistance battery useful in radio-active and ionisation work is the disc battery designed by Major C. E. S. Phillips (Cambridge Instrument Co.). It consists of adjacent paper discs coated with metal foil, is very portable, and is not damaged by short-circuiting. The horrors of the dentist's chair may be shortened by the use of radiography in the apparatus provided by Watson and Sons all external high tension leads are eliminated for the benefit of dentists untrained in such matters, and for the peace of mind of their patients. A Potter Bucky diaphragm is also provided for cutting out secondary radiation from the patient's body, which otherwise impairs the definition of the radiograph: it consists of a grid of lead plates so arranged as to absorb radiation which deviates from the direct line, and it is kept in motion during exposure so that its shadow does not appear on the film.

A soft-ray tube for crystal work, designed by Shearer, was shown by Hilger connected with a highly efficient evacuating arrangement. This comprised a Hyvac backing pump (on the Gaede model but with optically perfect contact surfaces) in combination with a Vitreosil mercury condensation pump (Edwards and Co.) with a fused silica casing, the over-all speed being about 200 c.c. per second and the ultimate vacuum about 0·000002 mm. An even faster pump is the Kaye-Backhurst, which is all of metal and employs an *annular* jet of vapour from boiling mercury to entrap molecules diffusing from the evacuated space. The speed amounts to some thousands of cubic centimetres per second.

Messrs. Hilger also showed how to use a Lummer-Gehrcke plate in combination with a spectroscope to demonstrate the Zeeman effect, obtaining very clear definition. Other optical items were a Nicol prism of 1¼-in. aperture (Bellingham and Stanley), a scaleometer (Ottway and Co.) comprising a pocket microscope with a scale in the focal plane of the eyepiece and an oblique glass plate for illuminating the object, and a rod illuminator (Baker) for microscopes. The latter very curious and effective device consists of a thick glass rod bent to any convenient shape and capable of carrying light by total internal reflection from a light source to a microscope: in fact it forms a kind of hose for conveying light. A selenium photometer (Watson and Sons), recently described by Dr. Toy, has been specially designed for measuring the density of photographic negatives. Two beams of light from the same source reach a selenium cell by different paths, and a screen can be turned so as to cut out one beam and let in the other at the same rate. The negative is interposed in the path of one beam and an adjustable wedge in that of the other, so that when the opacities of these obstructions are equal, no change in the illumination of the selenium cell is produced by turning the screen.

Teachers will be interested to find that kinematograph projectors for private use are coming within the reach of small pockets. A Pathé projector (Baker) can now be obtained at a comparatively moderate price, while a more expensive outfit (Kodak) enables the user to take his own films as well as to project them, the films being reversed to positive without the use of a negative. A Leitz photomicrograph (Ogilvy and Co.) has been so arranged that all the operations necessary in photographing microscopic objects on a whole plate can be performed from a single position of the observer, and the apparatus is suspended on springs while the exposure is actually being made. While discussing optical apparatus it is worth while to note that pointolite lamps can now be obtained for use on A.C. mains.

A very simple planimeter shown by Harling consists of a single rigid piece of metal carrying a tracing point at one end and a hatchet-shaped projection, the plane of which passes through the point, at the

other. The point is passed round a closed curve in the ordinary way, and the distance between the positions of the hatchet edge before and after this operation is a measure of the area encompassed It is claimed that this simple device can give an accuracy of 2 per cent.

Surveying instruments included a tacheometer (Cooke, Troughton and Simms) in which the horizontal distance of a surveyor's vertical scale is given directly, allowance for the slope being made by an automatic cam-operated adjustment of the distance between the stadie lines in the focal plane of the eyepiece with which the image of the scale is compared Dr Hutchinson's goniometer (Swift and Son) was also worth noting on account of its versatility it serves as an ordinary goniometer, an axial angle apparatus, a Kolrausch total reflectometer, and a prism refractometer. An ingenious balance (Oertling and Co.) called the "Chainomatic" dispenses with all weights and riders below 0·1 gm. by employing a chain attached at one end to an arm of the balance and at the other to a pillar which can be raised and lowered to a measured extent without opening the case The position of the pillar indicates how much of the weight of the chain is being borne by the balance arm In the tank gauge made by Negretti and Zambra for indicating liquid levels, air is pumped into a tube extending down into the liquid until it escapes from the bottom the tube is then put into communication with a pressure gauge which registers the head of liquid in the tank Another instrument of mechanical interest is the recording accelerometer of the Cambridge Instrument Co., in which an eccentric mass, the movements of which are made deadbeat by Foucault-current damping, records accelerations by the "stylus-on-celluloid" method developed by this firm

A fuller account of many of the exhibits will be found in the December issue of the *Journal of Scientific Instruments* published by the Institute of Physics. The issue is entirely devoted to the South Kensington exhibition

The following firms participated in the exhibition: C. Baker (optical instruments), R and J Beck, Ltd (optical instruments), Bellingham and Stanley, Ltd. (optical instruments), W Butcher and Sons, Ltd (the optiscope projection apparatus and the autoprint photographic enlarger), the Cambridge Instrument Co., Ltd. (thermometric and various precision instruments), the Cambridge University Press, Carbic, Ltd. (the Otis King's calculator), the Chromoscope Co., Ltd (the mutochrome, for varying the colours in patterns and designs), Cooke, Troughton and Simms, Ltd. (surveying instruments), A C Cossor, Ltd. (thermionic valves), Creed and Co., Ltd. (printing telegraphs), Crompton and Co., Ltd. (electric laboratory apparatus), George Culver, Ltd. (opticians' goods), J. H. Dallmeyer, Ltd. (cameras and lenses), the Damard Lacquer Co., Ltd. ("Formite" bakelite synthetic resin products for insulation, etc., the hardness of which is suggested by a humorist to have given rise to the company's name), Darmont Electric Batteries, Ltd, F. Davidson and Co. (optical instruments), the Dubilier Condenser Co. (1921), Ltd. (impedances), Edison Swan Electric Co., Ltd (pointolite lamps), W. Edwards and Co., Ltd. (vacuum pumps), Elliott Bros (London), Ltd (electrical testing apparatus), Everett, Edgecumbe and Co., Ltd (electric testing apparatus), Evershed and Vignoles, Ltd. (electric tests, wireless, traction recorder for electric trains), Foster Instrument Co. (pyrometers), E. B. Fry, Ltd. (time measuring and lantern slides), A. Gallenkamp and Co., Ltd. (electric furnaces, etc), Gambrell Bros, Ltd (electric testing), F. Harrison Glew (radio-active apparatus and cobalt steel magnets), John J Griffin and Sons, Ltd. (potentiometers, etc), W H. Harling (drawing instruments), Adam Hilger, Ltd. (optical and spectrographic instruments), Henry Hughes and Son, Ltd. (compasses, range-finder, etc), Igranic Electric Co, Ltd (wireless parts), the India Rubber, Gutta Percha and Telegraph Works Co., Ltd. (telegraph apparatus), Geo. Kent, Ltd (air, gas and steam meters), Kodak, Ltd. (cameras, etc), H K, Lewis and Co, Ltd. (scientific publications), Macmillan and Co, Ltd (scientific publications), Marconi's Wireless Telegraph Co, Ltd., the M O Valve Co., Ltd (wireless valves), the Mullard Radio Valve Co., Ltd (Holweck molecular pump and valves), Nalder Bros and Thompson, Ltd. (electric testing instruments, etc), Negretti and Zambra (meteorological instruments), Newton and Co (optical projectors), L. Oertling, Ltd (balances and the Eötvös torsion balance), Ogilvy and Co (microscopes and accessories), W. Ottway and Co., Ltd (surveying instruments, etc), Record Electrical Co, Ltd (switchboard apparatus), Ross, Ltd. (optical and photographic instruments), Short and Mason, Ltd. (meteorological instruments), Siemens Bros and Co., Ltd. (electric thermometry), H W. Sullivan, Ltd. (high frequency, cable and other electric testing apparatus), J. Swift and Son, Ltd. (industrial microscopes, etc), H. Tinsley and Co (electric testing, etc., apparatus), Watson and Sons (Electro-Medical), Ltd (X-ray apparatus), W. Watson and Sons, Ltd (optical instruments), Weston Electrical Instrument Co, Ltd. (electric testing apparatus), Wireless Press, Ltd., *The Wireless World and Radio Review*, Wray (Optical Works), Ltd. (cameras, lenses, and the nephelometer for measuring opalescence), Zenith Manufacturing Co. (resistances, etc.).

Annual Meeting of the Science Masters' Association.

THE twenty-fifth annual meeting of the Science Masters' Association was held on January 5, 6, and 7 at the University of Leeds, at the kind invitation of the University authorities Members were housed at the University Hostels, an act of hospitality which was very much appreciated The fact that the meeting was held at Leeds gave those members residing in Scotland and the North of England an excellent opportunity of attending, and the number present was very large The meeting began with a dinner in the Refectory, at which the Association was entertained by the University Afterwards there was a reception in the Great Hall by the Vice-Chancellor, Dr J. B Baillie, and the President of the Association, Sir Berkeley Moynihan, Bart, professor of clinical surgery in the University.

After a delightful speech of welcome by the Vice-Chancellor, which was suitably acknowledged by the chairman of the Association, Mr E. A Gardiner (Louth Grammar School), Sir Berkeley Moynihan delivered his presidential address The subject he chose was the debt which science owes to medicine, and was introduced by an historical survey of the progress of medicine from the earliest days to the present time. Claiming that Hippocrates and Galen were the inventors of the inductive and deductive methods respectively in science, the president passed in rapid review the events of succeeding centuries and astonished his audience by showing how many eminent men of science had been physicians or surgeons. Although, for several centuries, the growth of medicine scarcely kept pace with that of the slowest

of her intellectual children, the establishment of pathological anatomy at the hands of John Hunter and others, and, in more recent times, the great work of Lister, finally resulted in the reunion of the two methods of scientific inquiry—observation and experiment—so long divorced in medicine

After referring to the great difficulty in medicine of obtaining an accurate anamnesis, the president expressed his views on the nature of the help which might be expected from researches carried out in the laboratory .He pointed out that discovery of the cause of a disease, though often extremely valuable, does not necessarily mean that we can immediately effect a cure, or even that we should be able to devise a more efficacious method of treatment Treatment of tuberculosis, for example, has been very little changed by the discovery and isolation of the tubercle bacillus In the same way, even if science solves the problem of the cause of cancer, it does not follow that that fell disease will at once become curable. So far as cancer is concerned, indeed, Sir Berkeley said that we should never forget that we already know how to cure it in almost all parts of the body in which it commonly occurs Nothing in clinical practice is more certain than this—that cancer in the first instance is a local disease, and that, with few exceptions, an early operation for any cancerous growth is attended by only the slightest risk, if indeed by any, and may confidently be expected to confer a permanent immunity from a return of the disease

The chairman then called upon Prof. A Smithells, past president of the Association, to move the vote of thanks. Prof Smithells referred feelingly to the warm friendship which had existed for so long between the president and himself, and expressed the thanks of the Association in very happily chosen words The vote was seconded by Prof H E Armstrong, who has been a staunch friend of the Association, no less than its tireless mentor, since its inception a quarter of a century ago. The audience showed its appreciation of Sir Berkeley's address by carrying the vote with enthusiasm.

Tuesday morning was devoted to the business meeting, and to lectures given to the Association by Profs. J. H. Priestley, R Whiddington, and R W. Whytlaw-Gray. During the afternoon and evening, demonstrations were given in the laboratories by members of the University staff, and tours were made through the Departments of Textile Industries, Leather Industries, Colour Chemistry, and Engineering. Members of the Association expressed great pleasure at the laboratory demonstrations, where they obtained many new ideas for their own courses at school. Special mention must be accorded to the delightfully simple apparatus devised for showing the Brownian movement in tobacco smoke, which attracted a great deal of attention and requires nothing more elaborate than two good microscope objectives and a suitable source of light

On Wednesday there was a fruitful discussion on the connexion between science teaching in schools and universities, in which both sides were well represented The discussion was opened by Prof Smithells, who was followed by Dr Terry Thomas (Head Master of Leeds Grammar School), Mr F S Young, Mr Willings, Mr F B Stead (H M I), Prof W. P Milne (University of Leeds), and others In the afternoon, excursions were made to the Leeds Forge, the Yorkshire Copper Works, the Yorkshire Iron and Coal Co , Ltd., the West Ardsley Collieries, Messrs Ackroyd and Best (glass-blowing), the Prospect Mills (spinning, weaving, dyeing, and finishing), and Messrs J Nicholson and Sons, Ltd (sulphuric acid works) The educational importance of these visits, which enabled members to realise more closely the relationship between science and industry, can scarcely be exaggerated, and thanks were expressed to the various firms for their kindness in receiving the Association.

During the whole of the meeting there were excellent exhibitions of books, chemicals, and scientific apparatus by the leading firms, among which the exhibit by the local house of Reynolds and Branson may be specially noted There was also a stall devoted to books written by members of the Association, which testified to their literary activity A noteworthy feature was a list of books suitable for school science libraries, which should prove of great value to those engaged in teaching science in schools

It was announced that the Bishop of Birmingham had been asked, and had agreed, to act as president for the coming year

The meeting was one of the most successful in the history of the Association, and warm thanks were conveyed to the Vice-Chancellor and all other members of the University who had done so much to make the visit a memorable one Congratulations were also offered to the University on its recent jubilee celebrations.

Automatic Telephony and Teletyping.[1]

IT may be doubted whether the present generation works harder than the last, but, at any rate, it works at a much higher speed, and all kinds of devices are used to accelerate its rate of working. Whether this movement is altogether for the ultimate benefit of the human race is a moot question, but that it exists every one knows who has had experience of modern business methods. The incentive is the increase of profits that comes from doing an increased volume of work in a given time, by the aid of machinery. Speed and haste have very different meanings, and if the quality of the work does not suffer by the higher rate at which it is done, then the increase is beneficial, especially when it increases the time of the worker for exercise and recreation.

Amongst the devices for speeding up business, automatic telephony and printing telegraphy, or teletyping, will play a prominent part in the future. It is perhaps not generally known that the work of converting the manually operated telephone system of London into an automatic switching system has already been started The task is a stupendous one, and it will take fifteen years to complete

The accuracy of the service given in any telephone exchange, whether manual or automatic, depends largely on the ability of subscribers to use the telephone properly The delays that occur at present are often due to a lack of clearness in articulating both the name of the exchange and the number, and to the congestion of traffic during the "busy hour" In an automatic, or, as the Americans more properly call it, a machine switching exchange, these difficulties do not arise, and if we make the probable assumption that a well-looked-after machine is more accurate than a human being, it seems certain that the machine switching system will give a better service than the manually operated system we have at present.

During the progress of conversion a called subscriber will often be connected with a manually operated exchange. The calling subscriber operates his instrument in the usual way, and the call passes to an operator at the manual exchange. Fitted to the panel in front of this operator is a group of forty lamps divided into four sections of ten lamps each,

[1] From the Presidential Address to the Junior Institution of Engineers, delivered by Dr. Alexander Russell on Wednesday, January 7.

and each section is numbered from 1 to 10. When the number dialled by the calling subscriber is received by this apparatus, four lamps glow, one in each section, and the operator sees at a glance the number of the subscriber required The calling subscriber does not speak, and the connexion is made with the same ease as if it were all automatic

When two subscribers attempt to call another at the same time, one gets through and the other hears the engaged signal But when a call is made through a manual exchange, and the operator finds the required line is engaged, the call is stored until the line is clear

One great advantage of the machine switching system is that the service will be as good in the night time as during the day. Except for, possibly, one or two short periods at the rush hours, the highest grade of service will be given Errors due to faulty articulation will be a thing of the past It has to be remembered that the system adopted by the British Post Office is one that is capable of being continually improved Although the mechanisms remain the same, the rapid expansion of the system may lead to changes in the methods of operation in the immediate future.

These great auto-exchanges, with thousands of movable contacts in continual operation, appear uncanny to the non-technical person, but telephone engineers regard them in the same way as we would look on a large indicator for electric bells Seeing that there are now more than twenty million telephone exchange stations in the world, it is instructive to remember that the first was built less than fifty years ago We can be quite certain that the next fifty years will show an equally marvellous progress

Wonderful though automatic telephony is, electricians believe that in a few years' time it will have an equally wonderful rival in the new printing telegraphy The " ticker " is well known in large business offices where the latest quotations are printed in a continuous stream on a strip of paper The latest information is thus always available and can be acted on immediately. In the United States both the Western Union and the Bell Telephone Companies will shortly offer telegraph typewriter service to business men, and it seems highly probable that this will be a commercial success It will lead to teletype telegraphy, in which automatic switching exchanges not unlike those used in automatic telephony are employed.

It is perfectly feasible with this system for an ordinary girl typist to send messages up to 5000 miles at a speed of at least 30 words a minute. The British Post Office has already teletypes in use on several long lines As the method extends, machine switching stations will become a necessity and are certain to be employed It looks as if, in a few years' time, every wealthy person will have a " ticker " line for news superposed on his telephone line, his radio set being reserved mainly for entertainment purposes.

At first sight it might be thought that an air mail service would be a great rival to teletype telegraphy, but this is not the case The actual time of a letter by air mail to Paris is about four hours. It takes about 40 minutes to get from Charing Cross to Croydon Aerodrome. From Croydon to the Paris Aerodrome takes about 2½ hours, and from the aerodrome in Paris to the city another 30 minutes Finally, we have to allow at least 20 minutes for posting and delivery. It would generally, therefore, take more than four hours By the new telegraphy a long printed telegram could be received in 10 minutes. For distances greater than 50 miles the new printing telegraphy would probably be better than telephony.

A serious drawback to the use at present of teletyping is the cost of a cheap printer and of a trustworthy typewriter keyboard, but in a few years' time, it is possible that there may be such a demand for hundreds of thousands of them as would make them very considerably cheaper; they might then cost little more than an ordinary good quality typewriter. There would be a local rate for payment and, doubtless, also a time and distance rate.

University and Educational Intelligence.

LONDON.—A number of free public lectures have been arranged for the coming term. Among them are the following, the number of lectures in the case of a course being indicated in brackets, and the lecture hour being 5 30 unless otherwise stated :—

At University College.—Series of eight lectures beginning on January 27 : Prof G. Elliot Smith, on the evolution of man; Mr. W. J. Perry, on the beginnings of civilisation, and on the spread of culture; Dr C F Sonntag, on man's place in Nature (2); Prof. J. E. G. de Montmorency, on the significance of the humanism of the negro races; Mr. Reginald A. Smith, on the Old Stone Age, and Mr. C D. Forde, on the megalithic monuments of Brittany; Dr A. S Parkes, on the physiology of reproduction (6), beginning January 22 at 5 P.M, Prof. A. V. Hill, on the physiology of muscle and nerve (12), beginning January 23, at 11 A.M.; Prof. T B. Wood, on the nutrition of the young animal (3), beginning March 4; Prof. A C. Seward, on a botanical topic (3), commencing March 17, Prof H Westergaard, University of Copenhagen, on vital statistics (2), commencing March 9; Mr. A. Gomme, on technical and scientific libraries, on February 18 (one of a series of five lectures on the use of libraries).

At King's College—Dr. J. A. Hewitt, on carbohydrate metabolism (8), beginning January 19 at 5 P.M; Prof. E V. Appleton, on the rôle of the atmosphere in wireless telegraphy, on January 19; Mr C J. Gadd, on the excavations at Ur, on January 26; Mr. S. Smith, on the nature and influence of Babylonian literature, on February 9, series of three lectures on Chinese civilisation: Lieut.-Commdr. A S. Elwell Sutton, general views (February 5); Prof W. E. Soothill, China's contribution to Western civilisation (February 12); Dr. I. P. Bruce, education in China (February 19); Prof. A. E. Jolliffe, on English mathematics before Newton, on February 16; Prof. E Prestage, on Vasco Da Gama and the discovery of the sea-route to India, on February 13; Prof E. W. Scripture, experimental investigations of German poetry, on February 26.

At the Royal School of Mines, S. Kensington.—Prof. L Denoël, University of Liège, on tubbing deep shafts and subsidence (4), beginning February 23; Prof. C. A. Edwards, on chemical combination in metallic alloys and its nature (4), beginning March 3.

St. Bartholomew's Hospital Medical College.—Prof. C. Lovatt Evans, on the physiology of plain muscle (4), which began on January 14.

APPLICATIONS are invited for the professorship of botany in the West of Scotland Agricultural College, 6 Blythswood Square, Glasgow, in succession to the late Prof. A. N. McAlpine. The latest date for the receipt of applications is February 15.

ADULT education has been provided for in the United States on a rapidly increasing scale since the War. This is due to several causes, one being anxiety on the part of the State universities to give through their extension divisions conspicuous evidence of their usefulness, another the emergence of an insistent demand " that those who live in America must understand America." In Bulletins, 1923, Nos. 30 and 31, of the United States Bureau of Education, detailed accounts

are given of measures recently taken for the Americanisation of adult immigrants, especially in California. It had become apparent that the very efficiency of the education given to their children in the common schools was undermining the control of the immigrant parents and disrupting their family life. "Under the roof of every immigrant home is going on a death struggle between two worlds, two cultures, two civilizations,—in the same family circle different tongues are spoken, different newspapers and books are read, different manners and customs observed, . . . a delicate network of precious traditions is (so it seems to the immigrant) being ruthlessly torn asunder, a whole world of ideals is crashing to ruin, and amid this desolation the father and mother picture themselves wandering about lonely in vain search of their lost children." To meet this situation, the State of California has provided for the employment of "home teachers" to work in the homes of the pupils of the common schools, giving instruction in sanitation, the English language, home economics, and the fundamental principles of the American system of government and the rights and duties of citizenship. It is clear from the report that these teachers, where carefully chosen, are doing extremely valuable work—such work, moreover, as is perhaps needed quite as much in other countries, including Great Britain, where aliens are numerous.

THERE is a marked contrast in the system of government, *i.e.* in the localisation of administrative power, between the universities of Australia and those of Great Britain and the United States. In the United States, the president, and in the British Isles the vice-chancellor (or principal), is the controlling and unifying force. The constitution of the University of Sydney provides that the Senate of 24 members, of whom not necessarily more than 5 need be members of the teaching staff, has the entire management of and superintendence over its affairs. It has hitherto out of its own body, annually, elected a chancellor and a vice-chancellor, the latter usually being a lawyer. Melbourne is governed by a Council of not more than 31 members, of whom less than one-third can be and less than one-quarter must be members of the teaching staff. The Professorial Board may forward to Council an opinion on any matter relating to the University, as may also Convocation, which consists of all graduates, but neither the Professorial Board nor Convocation has executive functions. The Council elects, annually, a chancellor and a vice-chancellor. For some time past the teaching members of the Australian universities have felt the need of a permanent chief. Sydney had already taken a step in that direction by appointing a warden when the Conference of Australian Universities in 1920 adopted the following resolution in favour of the establishment of an executive office analogous to that of principal or vice-chancellor of a British university:—"That it is desirable, for more effective working and consonant with the general character of Australian Universities, that the appointment of an officer of high status, who could adequately represent both the administrative and the educational aspects of the University before other Universities and the public generally be seriously considered." The Senate of Sydney has recently given effect to this resolution by converting the vice-chancellorship into a stipendiary administrative office. To this office, Dr. M. W. MacCallum professor of modern literature for the period 1887–1920 and since 1920 emeritus professor, has been appointed as the first incumbent. Dr. MacCallum will shortly arrive in England for the purpose of delivering lectures by invitation of the British Academy.

Early Science at the Royal Society.

January 17, 1677/8. Dr. King instanced, that a gentleman who was a patient of his, could, two or three miles off London, discover when he entered into the smoke of London. Upon this some discourse arose about the reason why some chimnies smoke, that is, do not convey the smoke from the fire up the funnel, but suffer it to spread into the room.

January 18, 1664/5. Sir Robert Moray produced a discourse concerning coffee, written by Dr. Goddard at the King's command. Mr. Boyle mentioned, that he had been informed that the much drinking of coffee produced the palsy. The Bishop of Exeter seconded him. Mr Graunt affirmed that he knew two gentlemen, great drinkers of coffee, very paralytical. Dr Whistler suggested that it might be inquired whether the same persons took much tobacco.

1671/2. Mr Newton's new telescope was examined and applauded.

January 20, 1663/4. The general and particular warrant to demand bodies for dissection, drawn up by Sir Anthony Morgan, was read and approved. [The president afterwards stated that a warrant had been issued for demanding a body for dissection, which was to be performed the day after the execution, in Gresham College, by Dr Charleton, who had offered himself to open the muscles after a new method.]

1669/70. Mr Hooke produced for examination two ways of making an universal measure. Many exceptions were made by divers members against both these ways. For these and like difficulties both these ways were laid aside.

January 21, 1662/3. Dr Merret acquainted the society that he had received an information from Naples, concerning a person, who had an art of keeping new-born infants alive without respiration, for a good while. It was thought very desirable to have farther inquiry made.

1674/5. Sir John Bankes made a full report concerning the three fee-farm rents payable from fewes; concerning which the council accepted of the proposal, and resolved to dispose of the four hundred pounds legacy of the late Dr Wilkins, bishop of Chester, for purchasing of them, and accordingly desired Mr. Hoskyns to take care of a legal conveyance of the same to the Royal Society and their successors. —Mr. Oldenburg mentioned, that the earl of Aylesbury being obliged to go out of town, could not take care of providing a lecture, as he thought to have done, and had therefore sent to him his forty shillings; which money was delivered to the treasurer.

January 22, 1661/2. The experiment of making marbled paper was made by a man introduced by the amanuensis; which succeeded according to Mr. Evelyn's description of that method.—The pendulum experiment was discoursed of by the lord viscount Brouncker, who brought in the account and schemes of it. His lordship's paper was ordered to be registered, and a copy of it made against the Friday following, and brought to Sir Robert Moray, to be sent to Mons. Huygens.

1673/4. Mr. Lister having formerly sent some of his blood-stanching liquor, with a desire, that trials might be made with it before the Society, it was ordered, that the operator should provide a dog against the next meeting for that purpose.

January 23, 1666/7. Mr. Hooke was ordered to bring in something in writing relating to the controversy between Mr. Hevelius and Mons. Auzout, which might impart, that upon examination of the observations made in England, and compared with those in other parts, the society was inclined to believe, that Mr. Hevelius had been mistaken.

Societies and Academies.

LONDON

Linnean Society, December 18.—E. J. **Collins**: The physiological aspect of the incidence of late blight (*Phytophthora infestans*) of potatoes. So far as the foliage is concerned, that of the early varieties of potato and those most susceptible to blight have the highest water content, the most resistant, which are the latest to mature, have the lowest water content. High water content induces rapid tuberisation, and this entails early maturation and susceptibility to blight. The nitrogen content of the foliage reaches a maximum and then falls more or less rapidly according to the growth period of the variety. Maturation is thus accompanied by a decreasing nitrogen content of the foliage. The water : nitrogen ratio increases during the season and in general is highest at the time of infection. The degree of susceptibility to blight is indicated more precisely by the value of this ratio. Young foliage has a lower water and higher nitrogen content than foliage of a medium age, while in old foliage the reverse conditions hold. Sprayed foliage shows a lower water and a higher nitrogen content than unsprayed foliage. The value of spraying, apart from the action of the copper solution as a fungicide, lies in its physiological effect, since those metabolic changes accompanying old age, and heightening susceptibility, are delayed.—R. B. **Seymour Sewell**: A study of the Andaman sea-basin. The Andaman Sea appears, originally, to have been formed during the Eocene epoch as a comparatively shallow brackish-water estuary, into which all the main rivers of Burma flowed, by the simultaneous upheaval of parallel mountain-ranges. At the close of the Miocene period a second upheaval, volcanic in character, caused the appearance of a mountain-chain that is now represented by Narcondam Island, Barren Island, and Invisible Bank. The present deep basin is due to extensive subsidence, probably in post-Tertiary times. Continued subsidence, or subaerial erosion followed by a rise of sea-level led to the formation of various channels permitting the entry into the basin of a shallow-water fauna derived from both the Indian and Pacific Oceans, and of a deep-water fauna derived from the Bay of Bengal.

PARIS.

Academy of Sciences, December 8.—Paul Séjourné was elected a free academician in succession to the late Prince Bonaparte.—Pierre **Humbert**. The $V_{m,n}$ functions of Hermite with imaginary indices.—A. **Kovanko**: Suites of functions of class I (Baire).—Stanislas **Millot**: Some problems of Laplace. A discussion of some problems in the theory of probability.—E. **Paloque**: A new instrument for the determination of time and of latitude. This instrument is based on the observation of the simultaneous passage of two stars in the same azimuth.—Jean **Chazy**: The arrival in the solar system of a foreign star.—Charles **Henry**: A formula of the theory of relativity.—Jean **Granier**. The absorption of electromagnetic waves by ice. For the temperatures and frequencies studied, a condenser of pure ice may be represented by an arrangement of two condensers in parallel, one with an inductive capacity equal to 2·05, the other with an inductive capacity of about 78, the latter being in series with a resistance the value of which decreases as the temperature increases.—Félix-Joachim de **Wisniewski**: The doublets of the alkali metals.—P. **Job**: The electrometric study of hydrolysis.—A. **Boutaric** and G. **Corbet**: The critical temperature of solution of ternary mixtures. Curves are given showing the relation between critical solution temperatures of various ternary mixtures and their composition.—Jean **Thibaud**: The penetrating γ-radiation of mesothorium-2.—L. J. **Simon** and A. J. A. **Guillaumin**. Some derivatives of tetracetylmucic acid.—Léon **Piaux**. The spontaneous oxidation in alkaline solution of 1-methyluric and 1·3-methyluric acids. On oxidation in alkaline solution, 1-methyluric acid behaves similarly to uric acid, but 1·3-dimethyluric acid is completely split up, giving methylamine, potassium oxalurate and oxalate.—Georges **Patart**: The synthesis of methyl alcohol by reduction of carbon monoxide. A mixture of carbon monoxide (1 vol.) and hydrogen (1·5 to 2 vol.), under a pressure of 156 to 250 atmospheres, is circulated over a catalyst (zinc oxide) at a temperature between 400° and 420° C. On cooling to 20° C., a liquid is obtained containing water and methyl alcohol, with traces of impurities. Neither aldehyde nor acetone is present in this alcohol. The author considers that the commercial preparation of synthetic methyl alcohol by this method offers no serious difficulties.—Henri **Hubert**: Contribution to the study of the microseismic disturbances at Dakar (Senegal). The small earth vibrations at Dakar would appear to be mainly due to the impact of waves of the sea at points near this locality.—Ch. **Maurain**: The propagation of aerial waves as shown by the experiments at La Courtine. Two maps are given showing areas in which the velocity of propagation of the waves was that of the velocity of sound, and other areas in which the velocity was much lower than the velocity of sound; the latter are called zones of abnormal reception.—E. **Delcambre**: The meteorological work of the Jacques-Cartier service.—Ch. **Kilian** and R. G. **Werner**: Pure cultures of the fungi of lichens.—Mme L. **Randoin**, J. **Alquier**, Mlles **Asselin** and **Charles**: The nitrogenous materials of wheat offal. Comparative study of their biological value as factors of upkeep, of growth and of reproduction. Wheat offals (bran, etc.) regarded as a source of nitrogen have not the same biological value in a normal ration.—M. and Mme G. **Villedieu**: The action of solutions of copper sulphate on mildew. Millardet in 1886 pointed out the toxic action of very dilute solutions (1 in 4,000,000) of copper sulphate on the mildew of the vine (*Plasmopara viticola*). The authors show that the copper sulphate was not really in solution, but was present as very fine flocculated precipitates of basic copper sulphate, removable by filtration. The toxic action is exerted by this insoluble basic copper sulphate.—A. **Malaquin**: The genital glands and primordial sexual cells in the annelid *Salmacina Dysteri*.—J. **Legendre**: Zoophilia in mosquitoes and its application to prophylaxy.—A. **Paillot**. A new disease of the caterpillars of *Pieris Brassicae*, and on diseases of the nucleus (of the blood corpuscles) in insects.—Ch. **Dhéré**, A. **Schneider** and Th. van der **Bom**: The fluorescence of some metallic compounds of hæmatoporphyrin. Details of the photographed fluorescence spectra of the compounds of hæmatoporphyrin with zinc, tin, lead and cadmium.—Albert **Dalcq**. A new method of experimental parthenogenesis and its application. The maturation, activation and segmentation of the egg of *Asterias glacialis* can be produced by a single solution: the segmentation of the virgin egg is the result of the specific effects of various cations.—C. **Dawydoff**. Réduction in *Limeus lacteus*.

CALCUTTA.

Asiatic Society of Bengal, November 5.—S. H. **Lele**: Studies on Bombay fish. Revision of the genus Drepane (Cuv. and Val.). The anatomical

and morphological characters of the members of the genus Drepane are discussed. In view of constant differences, the genus should be split up into two species, as was done by Cuvier and Valencinnes.—B P **Uvarow**: Orthoptera (except Blattidæ) collected by Prof. Gregory's expedition to Yunnan. An account is given of the Yunnanese crickets and their allies collected by Prof. Gregory. The fauna of the Yunnanese mountains is found to be palæarctic while that of the valleys is truly oriental.—R. **Hanitsch**. Blattidæ collected by Prof. Gregory's expedition to Yunnan. Three species were found in Prof. Gregory's collection, two of which are described as new to science.—H **Hosten**: (1) Zādoē, of St. Thomas' Monastery in India (about A.D 363). A short supplementary note to the author's recent study on St Thomas and San Thomé, Mylapore, in the Society's Journal, quoting a reference to St Thomas purporting to go back to the fourth century A.D. (2) A letter of Fr. A de Andrada, S.J. (Tibet, August 29, 1627), and of Fr. Gaspar Diaz, S.J. (Annam, 1627). Spanish texts, with English translations, and notes. The letter by Diaz was published together with the other, probably in 1629, in two folio leaves, and a copy of the publication is in the British Museum. De Andrada's letter is not known in its original Portuguese form. Both give additional data concerning early European contact with Tibet and Further India. (3) A letter of Father Francisco Godinho, S.J., from Western Tibet (Tsaparang, August 16, 1626). This original French text adds to the data recently made available concerning early contact with Tibet through the efforts of the Roman Catholic missionaries in the beginning of the seventeenth century.—A S **Ramanatha Ayyar**. A note on Arddhanārīśvara. The identification proposed by Father H Hosten in his recent paper on St. Thomas in the Society's Journal is criticised. The figure there interpreted as the representation of an Amazon is in reality one of Arddhanārīśvara. The theory of Egyptian influence at Mahābalipuram in the seventh century A.D. is therefore rejected.—M Hidayet **Hosain**. The development of the Hadīth concordance in Arabic literature. The traditional sayings attributed to the Prophet Muhammad form a body of literature ranking first in importance in Islamic theology after the study of the Quran itself. The number of these sayings is overwhelmingly great, and from early times Muslim theologians have felt the need for the classification of them, and for a system to refer them to their sources. The science of "locating" the traditions is called "'Ilm al-Atrāf," and the author traces the development of the literature expounding this science from A.H. 400 to the present day.—'Abdul **Wali**. Sketch of the life of Sarmad Sa'id, surnamed Sarmad, a contemporary of Shah Jahan and Aurangzeb, was a Persian of Jewish birth. He came to India and after much wandering settled at Delhi. He was of a mystic temperament and embraced Islam, into which he introduced his mystic speculations. On a charge of heresy he was beheaded by order of Aurangzeb.

Official Publications Received.

Proceedings of the Eleventh Indian Science Congress (Bangalore, 1924). Pp. xv+262. (Calcutta: Asiatic Society of Bengal.) 6 12 rupees.

Journal of the College of Agriculture, Hokkaido Imperial University, Sapporo, Japan. Vol. 12, Part 2. Über den Einfluss meteorologischer Faktoren auf den Baumzuwachs (I). Über den Einfluss auf den Stammumfang eines Tannenbaumes. Von Hirokichi Nakashima. Pp. 69-263+plates 18-26. (Sapporo.)

Public Health Administration and the Natural History of Disease in Baltimore, Maryland, 1797-1920. By Dr. William Travis Howard, Jr. (Publication No. 351.) Pp. vi+565+2 maps. (Washington: Carnegie Institution.) 5.25 dollars.

General and Physiological Features of the Vegetation of the more Arid Portions of Southern Africa, with Notes on Climatic Environment. By William Austin Cannon. (Publication No. 354.) Pp. viii+159+31 plates. (Washington: Carnegie Institution.) 2 50 dollars.

Root Behavior and Crop Yield under Irrigation. By Frank C. Jean and John E. Weaver. (Publication No. 357.) Pp. v+66+6 plates. (Washington: Carnegie Institution.) 1 25 dollars.

Department of Agriculture, Straits Settlements and Federated Malay States. Bulletin No. 36. "Red Stripe" Weevil of Coconuts (*Rhynchophorus schach*, Oliv.). By G. H. Corbett and D. Ponniah. Pp. 51+6 plates. (Kuala Lumpur.) 50 cents.

Department of Commerce. U.S. Coast and Geodetic Survey. Terrestrial Magnetism. Serial No. 208. Results of Magnetic Observations made by the United States Coast and Geodetic Survey in 1923. By Daniel L. Hazard. (Special Publication No. 102.) Pp. 44. (Washington: Government Printing Office.) 10 cents.

Proceedings of the Royal Society of Edinburgh, Session 1924–1925. Vol. 45, Part 1, No. 2. The Irreducible System of Concomitants of Two Double Binary (2,1) Forms. By W. Saddler. Pp. 3-13. Vol. 45, Part 1, No. 3. A Series Formula for the Roots of Algebraic and Transcendental Equations. By A. C. Aitken. Pp. 14-22. Vol. 45, Part 1, No. 4. The Electrolysis of Salts of Alkyloxyacids. By Dr. David A. Fairweather. Pp. 23-33. (Edinburgh: R. Grant and Son; London: Williams and Norgate, Ltd.) 1s. each.

Anuario del Observatorio de Madrid para 1925. Pp. 477. (Madrid: Instituto Geográfico.)

The Scientific Proceedings of the Royal Dublin Society. Vol. 17, N.S., Nos. 42-47, August. 42. Experiments on the possible Effect of Vitamins on Quantity of Milk and Butter Fat, by E. J. Sheehy. 43. A Mechanical Device for Sealing off Radium Emanation Tubes, by Dr. H. H. Poole; 44: Notes on the Filtration and other Errors in the Determination of the Hydrogen Ion Concentration of Soils, by Dr. W. R. G. Atkins. 45. Variations in the Permeability of Leaf Cells, by Prof. Henry H. Dixon; 46. Notes on Acarine or Isle of Wight Bee Disease, by Lt.-Col. C. Samman and Prof. J. Bronte Gatenby. 47. Note on a Physical Method of separating the Fats in Butter-fat, by Prof. Felix E. Hackett and T. A. Crowley. Pp. 333-368. 4s. Vol. 18, N.S., Nos. 1-4, November 1. Seasonal Changes in the Water and Heleoplankton of Fresh-water Ponds, by W. R. G. Atkins and G. T. Harris. 2. The Synthesis of Urea from Carbon Dioxide and Ammonia under Atmospheric Pressure (Part 1), by Dr. Kenneth C. Bailey; 3. Oogenesis in Lithobius forficatus, by S. D. King. 4. The Determination of the most Economic Size of Pipe line for Water power Installations, by H. H. Jeffcott. Pp. 48. 5s. (Dublin: Royal Dublin Society; London: Williams and Norgate, Ltd.)

Department of Commerce. Bureau of Standards. Miscellaneous Publications No. 58. Technical Conference of State Utility Commission Engineers, held at the Bureau of Standards, Washington, D.C., March 2 and 3, 1923. Pp. iii+80. (Washington: Government Printing Office.) 15 cents.

National Museum of Wales. Seventeenth Annual Report, 1923-24, presented by the Council to the Court of Governors on the 24th October 1924. Pp. 38+6 plates. (Cardiff.)

City of Leicester Museum and Art Gallery. Twentieth Report to the City Council, 1st April 1912 to 31st March 1924. Pp. 66. (Leicester.)

The National University of Ireland. Calendar for the Year 1924. Pp. viii+824+369+117. (Dublin.)

Annuaire pour l'an 1925, publié par le Bureau des Longitudes. Pp. viii+680+A71+B30+C71. (Paris: Gauthier-Villars et Cie.) 6 50 francs.

The Pleistocene of the Middle Region of North America and its Vertebrated Animals. By Oliver P. Hay. (Publication 322A.) Pp. vii+385. (Washington: Carnegie Institution.) 2 50 dollars.

City and County of Bristol. The Bristol Museum and Art Gallery. Report of the Museum and Art Gallery Committee, for the Year ending 30th September 1924. Pp. 20+8 plates. (Bristol.)

Ministry of the Interior, Egypt. Department of Public Health. Reports and Notes of the Public Health Laboratories, Cairo. Ankylostomiasis and Bilharziasis, Cairo. Pp. iii+196. (Cairo: Government Publications Office.) 30 P T.

Diary of Societies.

SATURDAY, JANUARY 17.

PHYSIOLOGICAL SOCIETY (in Physiological Laboratory, St. Thomas's Hospital), at 4.—R. J. S. McDowall: The Sensory Sympathetic Nerves.—J. W. Pickering and H. Gordon Reeves: Thrombocytes and Blood Coagulation.—K. Furusawa: The Respiratory Quotient of the Excess Metabolism produced by Muscular Work.—A. St. G. Huggett and Prof. J. Mellanby: Preparation and Properties of Secretin.—L. N. Katz: The Asynchronism of the Contraction of the two Ventricles.—E. C. Smith: Insulin and Fat Metabolism.—R. Kinosita: Effect of Breathing against a Resistance.—J. Needham and Dorothy Needham: The pH and rH of the Cell-Interior—a Micro-Injection Study.—D. Burns: (1) The Inter-relation of the Parathyroids and the Gonads, (2) Guanidine in Urine.—Sybil Cooper: The Rate of Conduction in Nerve in the Supernormal Phase of Recovery.—C. D. Murray and H. Taylor: Method of Determination of the Oxygen and CO_2 in Mixed Venous Blood.

INSTITUTE OF BRITISH FOUNDRYMEN (Lancashire Branch, Junior Section) (at Manchester College of Technology), at 7.—J. G. Robinson: Moulding a large Fly-Wheel (Lecture).

MONDAY, JANUARY 19.

CAMBRIDGE PHILOSOPHICAL SOCIETY, at 4.30.

VICTORIA INSTITUTE (at Central Buildings, Westminster), at 4.30.—Dr. Dorothy M. Wrinch: Seismic Phenomena.

ROYAL GEOGRAPHICAL SOCIETY (at Lowther Lodge), at 5.—C. S. Wright: The Origin and Movements of the Ross Barrier.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Recent Discoveries of Fossil Man (I). The Antiquity of Man in South Africa. The Boskop Skull. The Relationship of the Boskop Race to Bushmen and Hottentot.

INSTITUTION OF MECHANICAL ENGINEERS (Graduates' Section), at 7.—A. J. D. Humby: Turbo-Blowers.

JUNIOR INSTITUTION OF ENGINEERS (North Western Section) (at 16 St. Mary's Parsonage, Manchester), at 7.15.—J. Prior. Confectionery Machinery.

INSTITUTION OF AUTOMOBILE ENGINEERS (Scottish Centre) (at Royal Technical College, Glasgow), at 7.30.—C. Macbeth. Low-Pressure Pneumatic Tyres.

INSTITUTION OF ELECTRICAL ENGINEERS (Mersey and North Wales (Liverpool) Centre) (at Liverpool University), at 7.30.—Sir Oliver Lodge (Lecture).

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—Dr. O. Faber: Applications in Building and Foundations of Modern Engineering Construction.

ARISTOTELIAN SOCIETY (at University of London Club), at 8.—W. O. Brigstocke: Pickwickian Senses.

ROYAL SOCIETY OF ARTS, at 8.—V. E. Pullen: Radiological Research.—a History (I). (Cantor Lectures.)

TUESDAY, JANUARY 20.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Prof. A. Fowler: The Analysis of Spectra (II.).

ROYAL STATISTICAL SOCIETY (at Royal Society of Arts), at 5.15.

MINERALOGICAL SOCIETY (at Geological Society), at 5.30.—Miss K. Yardley: An X-ray Examination of Calcium Formate.—J. Parry and Dr. F. E. Wright: Afwillite, a New Hydrous Calcium Silicate from Dutoitspan Mine, Kimberley, South Africa.—Prof. P. N. Chirvinsky: On Tyuyamunite from Tyuyu Muyun Radium Mine, Fergana.—Dr. L. J. Spencer: International Agreement in Mineralogical and Crystallographical Nomenclature.

INSTITUTE OF MARINE ENGINEERS, at 6.30.—Eng.-Lt. A. Marsden: Oil Fuel Burning in Steam Generator and Furnace.

INSTITUTION OF ELECTRICAL ENGINEERS (East Midland Sub Centre) (at Derby Technical College), at 6.45.—C. Beaver: Some Points in the Manufacture and Installation of High-Voltage Cables.

INSTITUTION OF ELECTRICAL ENGINEERS (North-Western Centre) (at Engineers' Club, Manchester), at 7.—H. W. Taylor: Three-Wire Direct-Current Distribution Networks.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Kinematograph Group), at 7.—Kinematograph Demonstration of some Experiments in Physics.

INSTITUTION OF AUTOMOBILE ENGINEERS (Wolverhampton Centre) (at Engineers' Club, Wolverhampton), at 7.30.—C. Macbeth: Low-Pressure Pneumatic Tyres.

INSTITUTION OF ELECTRICAL ENGINEERS (Scottish Centre) (Informal Meeting) (at 39 Elmbank Crescent, Glasgow), at 7.30.—Miss Kennedy: Electric Cooking.

MEDICO-LEGAL SOCIETY (at 11 Chandos Street, W.), at 8.30.—F. Ll. Jones: The Laws of Nations and the Health of Nations.

WEDNESDAY, JANUARY 21.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Recent Discoveries of Fossil Man (II.). The Rhodesian Skull. The Relationship of Rhodesian Man to Living and Extinct Types of Mankind.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—Prof. Léon W. Collet: Recent Views on Alpine Tectonics.

RADIO SOCIETY OF GREAT BRITAIN (at Institution of Electrical Engineers), at 6.—Sir Oliver Lodge: Matter and Radiation (Presidential Address).

INSTITUTION OF AUTOMOBILE ENGINEERS (Graduates Meeting) (at Chamber of Commerce, Birmingham), at 7.30.—J. G. Sheriff: Steering.

INSTITUTION OF ELECTRICAL ENGINEERS (Sheffield Sub Centre) (at Royal Victoria Hotel, Sheffield), at 7.30.—W. E. Burnand: Inventions and Patents.

INSTITUTION OF PRODUCTION ENGINEERS (at Engineers' Club, Coventry Street, W.), at 7.30.—H. A. Randall: Instruments and Gauges.

ROYAL METEOROLOGICAL SOCIETY (Annual General Meeting), at 7.40.—C. J. P. Cave: The Present Position of Meteorology and Meteorological Knowledge.

ROYAL MICROSCOPICAL SOCIETY (Annual Meeting), at 7.45.—A. Chaston Chapman: The Yeasts, a Chapter in Microscopical Science (Presidential Address).

ROYAL SOCIETY OF ARTS, at 8.—Mrs. Graydon-Stannus: Irish Glass, Old and New.

SOCIETY OF GLASS TECHNOLOGY (at Birmingham).

THURSDAY, JANUARY 22.

ROYAL SOCIETY, at 4.30.—Prof. H. C. H. Carpenter and Miss C. F. Elam: Experiments on the Distortion of Single-Crystal Test Pieces of Aluminium.—J. V. Howard and S. L. Smith: Recent Developments in Tensile Testing.—R. L. Smith-Rose and R. H. Barfield: On the Determination of the Directions of the Forces in Wireless Waves at the Earth's Surface.—*Papers to be read in title only.* Prof. D'Arcy Thompson: On the Thirteen Semi-regular Solids of Archimedes, and on their Development by the Transformation of Certain Plane Configurations.—W. S. Farren and Prof. G. I. Taylor: The Heat developed during Plastic Extension of Metals.—U. R. Evans: The Colours due to Thin Films on Metals.—A. Campbell: On the Determination of Resistance in Terms of Mutual Inductance.—S. Butterworth: On the Alternating Current Resistance of Solenoidal Coils.

LINNEAN SOCIETY OF LONDON, at 5.—The President and R. D'O. Good: The Recent Meeting in Canada of the British Association.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—J. S. Huxley: The Courtship of Animals and its Biological Bearings (II.).

ROYAL AERONAUTICAL SOCIETY, at 5.30.—Major R. V. Southwell: Some Recent Work of the Aerodynamics Department, National Physical Laboratory.

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—H. W. Clothier: The Design of Electrical Plant, Control Gear and Connexions for Protection against Shock, Fire and Faults.

INSTITUTION OF AUTOMOBILE ENGINEERS (Luton Graduates Meeting) (at Luton), at 7.30.—A. O. Seward: Carburation.

INSTITUTE OF CHEMISTRY (Edinburgh and East of Scotland Section) (and Society of Chemical Industry, Edinburgh and East of Scotland Section) (at North British Station Hotel, Edinburgh), at 7.30.—Prof. J. Hendrick. The Alsatian Potash Mines.

FRIDAY, JANUARY 23.

ROYAL DUBLIN SOCIETY, at 4.30.

PHYSICAL SOCIETY OF LONDON (at Imperial College of Science and Technology), at 5.—Dr. B. W. Clack: An Investigation of the Measurement of Small Differences of Refractive Index by the Rayleigh Interferometer.—J. Taylor and W. Clarkson: A Study of the Production of Flashing in Air Electric Discharge Tubes.—C. R. Darling: A Kinematographic Study of Plateau's Spherule (Demonstration).

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith. Recent Discoveries of Fossil Man (III.). Recent Discoveries in Australia and Java and their Bearing on the Theory of Man's Evolution.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—Reports to the Cutting Tools Research Committee.—Dr. W. Rosenhain and A. C. Stanney: Flow and Rupture of Metals during Cutting.—Dr. T. E. Stanton and J. H. Hyde: An Experimental Study of the Forces exerted on the Surface of a Cutting Tool.

THE SOCIETY OF DYERS AND COLOURISTS (London Section) (at Australia House, Strand), at 7.—J. Craft: Incorporation of Eulan into Woollen Textiles and other Fabrics, Permanent Protection against Moth Damage (Lecture).

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—Lantern Lecture.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—R. H. Parsons: Boiler-house Records and their Practical Value (Lecturette).

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Literary and Philosophical Society, Newcastle-upon-Tyne), at 7.30.—E. A. Eborall: Railway Electrification in Switzerland (Lecture).

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Middlesbrough Graduate Section) (at Cleveland Scientific and Technical Institution, Middlesbrough), at 7.30.—T. Lewis: Gas Producers.

C.B.C. SOCIETY FOR CONSTRUCTIVE BIRTH CONTROL AND RACIAL PROGRESS (at Essex Hall, Essex Street, W.C.), at 8.—Prof. A. M. Carr-Saunders: The History of the Limitation of Numbers.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Dr. A. W. Crossley: Science and the Cotton Industry.

PUBLIC LECTURES.

MONDAY, JANUARY 19.

KING'S COLLEGE, at 5.—Dr. J. A. Hewitt: Carbohydrate Metabolism (Succeeding Lectures on January 26, February 2, 9, 16, 23, March 2, 9.)

LONDON SCHOOL OF ECONOMICS AND POLITICAL SCIENCE, at 5.—Dr. E. B. Behrens: International Problems of Industry (I.) Historical Background, and the Competitive Element in the Determination of Conditions of Labour.

UNIVERSITY COLLEGE, at 5.—Prof. G. Elliot Smith: The Lectures on the Anatomy and Physiology of the Sympathetic Innervation of the Striated Muscle, prepared for delivery by the late Prof. J. Hunter. (Succeeding Lectures on January 26 and February 2.)

KING'S COLLEGE, at 5.30.—Prof. E. V. Appleton: The Rôle of the Atmosphere in Wireless Telegraphy.

TUESDAY, JANUARY 20.

UNIVERSITY OF LEEDS AND LEEDS PHILOSOPHICAL AND LITERARY SOCIETY (at Leeds University), at 6.—Prof. A. Gilligan: The Geology of Yorkshire: Cleveland and the Yorkshire Wolds.

WEDNESDAY, JANUARY 21.

LONDON SCHOOL OF ECONOMICS AND POLITICAL SCIENCE, at 5.—W. H. Ansell: The Principles of Design as applied to Buildings.

KING'S COLLEGE, at 5.30.—M. L. W. Laistner: The Decay of Geographical Knowledge and the Decline of Exploration, A.D. 500–600.

UNIVERSITY COLLEGE, at 5.30.—H. Jenkinson: The Public Record Office and Archives.

THURSDAY, JANUARY 22.

UNIVERSITY COLLEGE, at 5.—Dr. A. S. Parkes: The Physiology of Reproduction. (Succeeding Lectures on January 29, February 5, 12, 19, 26.)

FRIDAY, JANUARY 23.

Fuel Research.

ONE of the most important of the subjects dealt with in the recent annual Report of the Committee of the Privy Council for Scientific and Industrial Research is that of fuel. Fuel is in Great Britain practically the sole source of the power which is essential to all our large industries. The only fuel of national importance produced at the present time is coal, and on the economic use of our diminishing supplies of it the prosperity of the country largely depends. This is now becoming a platitude, but the complexity of the problem involved is by no means realised by many popular writers on the subject.

The coal as it exists in the ground is a highly complex substance, and its constitution varies very widely, even through the thickness of a single seam. The quantity and nature of the volatile content, of the "ash" content, the coking power, the moisture content, and the calorific value all vary, as well as the amount of impurities such as sulphur, arsenic, or phosphorus which, while never intrinsically large, may for some purposes be very important. Analyses and determinations of calorific value, while giving much useful information, by no means give all the information required to determine the suitability of a coal for any given purpose. For example, it is obvious that a large ash content is undesirable, as the cost of carriage of the ash is the same as that of the coal, and in addition the ash has to be removed from the furnace and disposed of. This is, however, not the whole story. The melting-point of the ash is of importance, and while, for example, a low melting-point is not objectionable for domestic purposes, as it tends to prevent the formation of a powdery ash in the grate, a high melting-point is wanted for industrial purposes to prevent the too ready formation of clinker. Similarly, the composition of the ash may have a considerable influence on the refractory linings of the furnace. Recent investigations indicate that the ash may have subtle effects on the decomposition of the coal under heat, and further investigation may show that these effects are of great importance to the carbonisation industries.

Of recent years increased attention has been given to the removal of ash by washing or other purification processes, but much work remains to be done before it will be possible to recommend the best methods to adopt and the degree of purification that is economically desirable.

Much fine coal is left underground, or if brought up is at present unsaleable, and this constitutes a great waste of potential resources. The difficulty in using this coal is due partly to the high ash content and partly to the difficulties of transport and storage.

There is here a large field for useful research which embraces coal-washing, the causes of spontaneous combustion, and methods of briquetting, but there can be no single solution that will suit all fine coals. The solution must depend on the circumstances of each case, and a knowledge of these circumstances can be gained only from a survey of the physical and chemical characteristics of the various coal seams.

Another field of research which has as yet been but little explored is that dealing with metallurgical coke. The prosperity of the great iron and steel industries depends very largely on the possibility of reducing the cost of the fuel per ton of metal dealt with It is well known that cokes vary widely in their properties and in the economy with which they can be used, but so far, it has proved impossible to say in detail why one coke is better than another It is, then, of importance to find out (*a*) the properties of the coke that are of fundamental importance for metallurgical purposes, (*b*) the characteristics of the raw coal necessary to obtain these properties in the coke, and (*c*) the best method of obtaining the coke from the coal. For this purpose again a knowledge of the characteristics of the various coal seams is necessary before the problem can be fully solved

For metallurgical purposes raw coal is often unsuitable, but there are many other purposes where, while raw coal could be used, it is both convenient and economical to treat the coal so as to obtain other forms of fuel. The real object of all such treatments is to increase the availability of the heat units, *i.e.* to provide a fuel which can be more efficiently and conveniently transported and utilised than can the coal itself. The most widely used of such treatments is the carbonisation of coal to produce coal-gas and coke, the manufacture of which incidentally produces as by-products a large proportion of the raw material required by our chemical industries. The importance of this and of the smokeless nature of the gas and coke needs no emphasis here, but the gasification of all our coal would not be advantageous, even if all coals were suitable for the process. There is necessarily a thermal loss in any carbonisation process, and this loss can only be justified if it is compensated for by the more economical use of the heat units remaining, and in economy of use must be included economy of transport. The over-all thermal efficiency of a carbonisation plant plus a boiler plant, where the combustible products of the carbonisation are all immediately burned under boilers, is necessarily lower than that of a boiler plant utilising the raw coal.

The carbonisation of coal at "low temperatures" has been much to the fore of recent years, with the object of obtaining home supplies of oil and a smokeless solid fuel for domestic and industrial purposes, and considerable progress has been made towards the solution of its particular problems. Here again it is not all coals that are suitable for the purpose, and all suitable coals will not respond to the same treatment.

Whatever aspect of the fuel problem is considered, it is found that a solution of its problems, if looked at from a national point of view, depends on a fuller knowledge of the characteristics of the coal available than we at present possess. The Fuel Research Board is therefore correct in placing the physical and chemical survey of the national coal resources in the forefront of its programme, and it is gratifying to learn that the Government has decided that this work shall "be pressed forward at the maximum speed compatible with obtaining proper value for the expenditure."

The Fuel Research Board considered "that the actual work in the coalfields would best be carried out by means of local committees, the personnel of which included colliery owners, managers, consumers, and representatives of the Board and of the Geological Survey. By this means it was hoped to obtain the sympathetic co-operation of the owners and managers without which the work could not be carried on." In the two areas in which local committees have been formed, the report states that this co-operation has been given freely. It is to be hoped that the same spirit will animate the owners and managers in the other coalfields of the country. There need be no fear that more economical methods of utilising our fuel resources will be detrimental to the coal-producing industry, as the cheapening in the cost of our manufactured products which would result would lead to a greater demand for them, and so keep up the demand for the coal, to say nothing of the possibilities of enabling the collieries to find favourable markets for coal at present unsaleable.

The practice adopted by the Survey, of taking samples in the form of a pillar of coal through the whole thickness of the seam, enables each portion of the seam to be examined separately, and thus brings out any peculiarities that may exist in the different layers. It has already been abundantly shown that very striking differences may exist, and that in some cases the different layers may be advantageously separated before the coal is marketed, the extra labour involved being more than compensated for by the increased value of the coal. The work of the Survey is, however, not confined to the laboratory examination of small samples, and in suitable cases samples of several hundred tons may be tried out to ascertain their behaviour in full-scale plant.

Logarithms de Luxe.

Logarithmetica Britannica: being a Standard Table of Logarithms to Twenty Decimal Places. By Alexander John Thompson. Part 9: Numbers 90,000 to 100,000. (Issued by the Biometric Laboratory, University of London, to commemorate the Tercentenary of Henry Briggs's publication of the "Arithmetica Logarithmica," 1624.) Pp. xviii + 100. (Cambridge: At the University Press, 1924.) n.p.

ON the appearance of the first section of this important book, it is appropriate to give some account of the evolution of logarithmic tables.

Henry Briggs, the computer of the first great table of logarithms, was born about 1556 at Warley Wood, a hamlet near Halifax, Yorkshire. He showed signs of mathematical ability at an early age, and proceeded to St. John's College, Cambridge, in 1579. Briggs was elected a fellow of his College in 1588 and remained there until 1596, when he became the first reader in geometry at Gresham College in London

In 1614 Napier's first work on logarithms was published, the "Mirifici Logarithmorum Canonis Descriptio." This book came into Briggs's hands soon afterwards: he began to read it with interest, which was changed into enthusiasm by the time he had finished He soon perceived that the system of logarithms which would now be described as having 10 for base would be more convenient in use than that on which Napier's system had been calculated After describing this improvement to his classes, Briggs travelled to Edinburgh in 1615 and discussed it with Napier. He remained there a month as Napier's guest, and on his return to London busied himself in calculating logarithms according to the new plan. In 1616 he again visited Napier, taking with him the calculations he had made. The results of these calculations were printed in 1617, for the benefit of his personal friends, as "Logarithmorum Chilias Prima." In this rare brochure were given the logarithms of the first 1000 numbers to 14 decimal places Specimen pages are reproduced as a frontispiece to the work now under notice.

In 1619 Briggs became the first Savilian professor of geometry at Oxford, settling at Merton College, and resided there for the remainder of his life. He continued to carry on his computing, and in 1624, after about eight years' labour, produced the "Arithmetica Logarithmica." This work contains the logarithms to 14 decimal places, together with their first differences, of all numbers from 1 to 20,000 and from 90,000 to 100,000. It is accompanied by a masterly introduction, in which the construction of tables, interpolation by means of differences, and other matters of the greatest importance were dealt with for the first time. Although this work is now very rare and costly, it is said that the edition of the tabular portion was too large and that surplus copies were hawked in the streets of London at eighteen pence each After completing this great book, Briggs, with the help of a few friends, began to fill up the large gap of 70,000 logarithms which had been left. These were almost completed when, in 1628, Adrian Vlacq, a Dutchman, published the logarithms of the first 100,000 numbers to 10 decimal places, in a book which he also called "Arithmetica Logarithmica." Although Vlacq had only copied 30,000 logarithms from Briggs's book (cutting them down from 14 to 10 decimal places) and had calculated 70,000 himself, he described his work merely as a second edition. Briggs may have felt some disappointment at the way in which he had been forestalled by Vlacq: he seems, however, to have been relieved that the burden of printing 70,000 logarithms had been removed from his shoulders. In such circumstances most men would have given up computing; but not so Briggs. When about seventy years of age, he commenced another great work, the logarithms of the trigonometrical functions, and had almost completed it at the time of his death in 1631 Vlacq printed these logarithms at his own expense and published them in 1633 under the title of "Trigonometria Britannica."

No complete reprint of Briggs's great table of the logarithms of numbers has ever been made, and, up to last year, only two 10-figure tables have been published since Vlacq produced his table in 1628 The need for an extended table has long been felt, and the present work is intended to meet this need Logarithms to a few figures are seldom used in present-day computation, and the modern calculating machines often fail to give results of sufficient accuracy without great expenditure of labour In statistical and computing laboratories—especially where new tables have to be prepared for publication—the original Briggs or original Vega are in greater demand than more contracted logarithmic tables. Yet their high cost, their rarity, and uncorrected errors have long rendered new tables desirable.

No tribute more fitting than the publication of this new 20-figure table could be paid to the memory of a great man on the tercentenary of his greatest work. After extensive inquiries, the compilers have been unable to trace any portrait of Briggs for reproduction in the book.

The section now issued gives the first 20 figures in the mantissa of log N for each integer N from 90,000 to 100,000, together with second and fourth central differences for use in interpolation. First differences are not tabulated: their inclusion would have greatly

increased the bulk of the volume and rendered the cost of producing it prohibitive. It is intended to issue eight similar sections at intervals of a few months to include the range from 10,000 to 90,000.

Linear interpolation is sufficient to evaluate the logarithm of any number, given as a decimal, correct to 10 figures—and the calculation involved is slight Methods for evaluating a logarithm to 15 or 20 decimals are described on the assumption that the computer has access to a calculating machine. Such machines are now used widely, and the amount of work involved is less serious than would appear at first sight Naturally, a computer who undertakes calculations to 20 significant figures must be prepared for a certain amount of arithmetical labour. To evaluate log γ where $\gamma = 0\ 57721\ 56649\ 01532\ 86061$, first put $\gamma/a = \gamma/0{\cdot}6 = 0\ 96202\ 61081\ 69221\ 43435$, which is within the range of the tables. Next, $\gamma/a = 0{\cdot}96202\ 61 \times 1\ 00000\ 00084\ 91683\ 78524 = bc$ Log b is found from log 96202 and log 96203 by Prof. J. D Everett's central-difference interpolation formula The numerical coefficients involved are taken from an earlier publication of the Biometric Laboratory, prepared by the same author (A J. Thompson's "Table of the Coefficients of Everett's Central-Difference Interpolation Formula," Tracts for Computers, V., Cambridge University Press, 1921) A short supplementary table gives the logarithms of numbers between 10^{10} and $10^{10}+100$, and log c is obtained by interpolation between log $(10^{10}+84)$ and log $(10^{10}+85)$. Finally, log γ = log a + log b + log $c = \bar{1}\ 76133\ 81087\ 83167\ 61054$, and this is correct to the twentieth decimal place

Of the scheme which has been begun we have but one criticism to offer We think the table should be extended so as to include 21-figure logarithms of integers between 100,000 and 110,000. The $(k+1)$th figure of N when $1{\cdot}0 < N < 1{\cdot}1$ has only the same significance as the kth figure in the main body of the table. If α, β are small and positive,

$$\delta = \log(1+\alpha) - \log(1+\beta) = \mu(\alpha-\beta),$$
$$\delta' = \log(1-\alpha) - \log(1-\beta) = -\mu(\alpha-\beta)$$

approximately Since, however,

$$1+\alpha = 1{\cdot}0\ \ldots\ ,\ 1+\beta = 1\ 0\ \ldots,$$
$$1-\alpha = 0{\cdot}9\ \ldots,\ 1-\beta = 0{\cdot}9\ \ldots,$$

the tabulated value of δ, when k-figure logarithms are used throughout, will be ten times as great as the tabulated value of δ' The value of the $(k+1)$th figure in the logarithm of a number just exceeding unity is apparent in many applications of the tables, *e.g.* in actuarial work and in stability problems in dynamics. This need has been recognised by the compiler of Chambers's 7-figure tables, which include 8-figure logarithms of numbers between 100,000 and 108,000.

Both Mr. Thompson and the Director of the Biometric Laboratory in University College (Prof. Karl Pearson), London, are to be heartily congratulated on the publication of this book, the former for his enthusiastic energy which has not been damped by the seriousness of the labour involved in calculating the table, and the latter for undertaking the production of it. Such an enterprise is not one of profit: a wide readiness on the part of the mathematical world to commemorate with the promoters the tercentenary of the "Arithmetica Logarithmica" can alone ensure the success of the venture.

Earthquakes and Geology.

La Géologie séismologique: les tremblements de terre. Par le Comte de Montessus de Ballore. Pp. xiv + 488 + 16 planches. (Paris. Armand Colin, 1924.) 50 francs.

TO those who value the work of M. de Montessus de Ballore, this posthumous volume will be a welcome surprise. It forms the third of a well-known series. The first, "Géographie séismologique," based on the distribution of 171 thousand earthquakes, was published in 1906. The second, "La Science séismologique"—the most detailed treatise that we possess on earthquakes in general—appeared in 1907. Then followed a long gap during which the author was mainly occupied in organising the Chilian Seismic Service. In the evening of his active life he has written the volume before us, the text of which he lived to send to the press, though the task of proof-correcting and the selection of the illustrations were done by others. M. Pierre Termier has contributed the preface, and M. Armand Renier a short biography of Montessus and a useful list of his books and memoirs.

"La Géologie séismologique" is less a treatise on the origin of earthquakes than a series of descriptions of important earthquakes with special reference to the phenomena of geological interest. Montessus divides earthquakes into two main classes, glyptogenic or geological and external dynamic earthquakes. The former are further rearranged into epeirogenic, tectonic, and epeirogenic and tectonic, according as the surface displacements are vertical, horizontal, or vertical and horizontal combined. Under the term external dynamic earthquakes are included volcanic earthquakes and rock-fall earthquakes (tremblements de terre d'écroulement). Between the two classes lie the majority of earthquakes, those which produce no apparent individual effect on geological structure, and which he therefore leaves unconsidered. He regards the connexion of these shocks with glyptogenic earthquakes as a very plausible induction and nothing more. Yet if, as in the Inverness earthquakes of 1901, the

epicentres can be traced shifting to and fro along a line of fault, if in their migrations they follow the same law as the after-shocks of the Japanese earthquake of 1891, the conclusion that they are glyptogenic is surely more than plausible. In any case, do not such earthquakes deserve consideration as much as purely volcanic earthquakes (to which 62 interesting pages are given), and more than rock-fall earthquakes, which are unimportant from a geological point of view?

The terms adopted by Montessus are, in one or two respects, unfortunate. The word *tectonic* has hitherto been applied to all earthquakes due to the growth or moulding of the earth's crust There seems no valid reason for confining it to earthquakes connected with horizontal displacements The name of the third class, epeirogenic and tectonic, is cumbrous. Terminology, however, is of less consequence than the classification implied, which is a useful one.

Under the heading of epeirogenic earthquakes are included the great earthquakes of New Madrid in 1811, Assam in 1897, and Kangra in 1905. The Chilian earthquakes of 1822, 1835, and 1837 would have been added if it were certain that they were accompanied by elevation of the land. But the author accepts Suess's arguments—which seem to me inconclusive—and considers that those who saw definite traces of elevation were mistaken. Possibly he would have revised this opinion could he have known of the recent observations in Japan (see NATURE, January 10, p 65) on the later settling of elevated tracts.

Typical examples of tectonic earthquakes are the Owen's Valley earthquake of 1872, the Sumatra earthquake of 1892, and the Californian earthquake of 1906; those of epeirogenic and tectonic earthquakes are the New Zealand earthquakes of 1848 and 1855, the Japanese earthquake of 1891, and the Alaskan earthquakes of 1899. Of volcanic earthquakes, accounts are given, among others, of the Hawaiian earthquake of 1868, the Ischian earthquakes of 1883, etc., and earthquakes connected with various eruptions in Japan and the Philippine Islands.

The chapters in which these earthquakes are described form, roughly, two-thirds of the book. Of the remaining third, half is given to secondary glyptogenic effects of earthquakes, such as the isostatic readjustment of alluvial plains, the subsidence of coasts and submarine talus (including accounts of the Jamaica earthquakes of 1692 and 1907 and the Messina earthquake of 1908), and avalanches, effects on glaciers, etc. The latter half contains interesting discussions of some miscellaneous questions, such as changes in topography produced by earthquakes, the influence of geological conditions on the trend of isoseismal lines, the migration of epicentres, and the geographical distribution of earthquakes. The last two chapters might well have been longer; perhaps they were hurriedly finished in the closing days of the author's life. Of the migration of epicentres, two examples only are given, of the Calabrian earthquakes on a small scale, and of earthquakes along the unstable circum-Pacific circle on a large scale. A page or two on the migration of after-shock epicentres, which is merely touched on, would have been a welcome addition. As the author remarks, such a study would tend to nothing less than the prevision of earthquakes. Still more effective for the purpose would have been a study of the migration of fore-shock epicentres. For example, in those of the Japanese earthquake of 1891, the distribution of epicentres during the years 1890 and 1891 outlined the future zones of dislocation and clearly pointed to the coming earthquake.

There are few omissions of any consequence. Some have been suggested above, the principal one being the absence of reference to shocks of small intensity. In the account of the Ischian earthquakes, Johnston-Lavis's monograph is not mentioned The important part played by after-shocks is not considered in detail. Such omissions, however, are of small account in comparison with the great service that the author has rendered. Here, under one cover, are gathered materials collected from widely scattered sources. Few, if any, writers have had Montessus's acquaintance with the literature of earthquakes, and there are not many libraries, either public or private, that contain all the works from which he has drawn his admirable illustrations. In no way is this last volume inferior to its two predecessors. To have produced it is a worthy ending to a life of unceasing labour in the cause of science C. DAVISON.

Egyptian Mummies.

Egyptian Mummies. By Prof. G. Elliot Smith and Warren R. Dawson. Pp. 190+65 plates. (London: G. Allen and Unwin, Ltd., 1924) 25s net.

PROF. ELLIOT SMITH and Mr Warren Dawson have written a very interesting and useful book on mummies, which appears in a most attractive guise (except for some of the illustrations). Its outward show would seem to indicate that it is intended for the general reader who is "keen on" mummies and mystery rather than for the scientific student, but the latter will find in it much detail of purely scientific (and more especially pathological) interest, besides a sketch of the history of the practice in Egypt which, being written by the chief authority on the subject, can be accepted without question. The book takes the place of the old and out-of-date work of Pettigrew,

which hitherto has been almost the only treatise specially devoted to the subject, though the archæological reader will find a very useful chapter on the matter in Sir Ernest Budge's long out-of-print book, "The Mummy."

On the archæological side the book is unexceptionable, until the writers (as we fear was to be expected) launch into a dogmatic statement (rather than, as one would have preferred, a reasoned justification) of the now well-known "diffusionist" theory of the spread of all human culture from Egypt, even so far as America via Polynesia, of which Prof. Elliot Smith is the protagonist. They inform us, as if the matter were settled fact, that mummification spread via India to Malaysia, Torres Straits, Polynesia, and finally Peru and Mexico, "and became widely diffused in both continents of America" (pp. 164, 165). There is no peradventure in this matter for these authors: it is as settled a fact for them as is any religious dogma for its *croyants*; and is calmly assumed to be a known fact Let it first be proved to be even a probable theory It is not yet accepted as such by the archæologists. It may eventually be proved to be a probable theory; we do not say that it will not or cannot, because we have no *beliefs* on these subjects whatever: we consider *beliefs* about anything relating to the early history of man and the origins and diffusion of his culture to be totally unjustified and unscientific: one is still dimly groping in the dark of theories and hypotheses, not dealing with mathematical certainties The "diffusionist" theory is just one of these hypotheses which *may* be true but cannot yet be proved to be so, any more than any other theory of the kind, and until it is proved so, should not be stated as uncontroverted fact, which it is not

On the archæological side, the authors clearly state the extremely probable origin of mummification in the drying-up of the body in the hot rainless desert sand of the primitive Egyptians' graves, which first gave the idea of preserving the dead in the pathetic hope that they could in some muddle-headed way be made to live again It was a protest against death, which the Egyptians loathed: "O ye who love life and hate death," begins the prayer which summons the living to come and bear their offerings of food to the tomb that the dimly imagined "double" or *ka* of the deceased might feed upon it and somehow "live." Then we are told how true mummification began with the addition of preservatives and bandages, first only in the case of the king and then of his nobles. The common people were not embalmed even in the most summary way until much later. Then we see how the practice grew and developed, until it reached its apogee in some respects in the time of the XVIIIth–XIXth Dynasties, though it was not until the XXIst that the mummy became a sort of human statue much like those proposed by Jeremy Bentham. Finally we see how it declined until Christianity abolished it, after a short struggle with those Egyptian Christians who wished to retain their ancient national practice.

Chapters on the funerary furniture and amulets of the mummy, the spells of the Book of the Dead, etc., are given, and a useful list of those kings whose tombs and mummies are known.

The pathological side of the inquiry is, of course, well represented, and physicians will find interesting the proofs of the existence of dental and tubercular caries, leprosy, Pott's disease, gall-stones, osteo-sarcoma, mastoid disease, talipes, and *Dystocia adiposo-genitalis* among the ancient Egyptians, to whom, however, syphilis seems to have been unknown. Prof. Elliot Smith gives several photographs of such pathological conditions.

The photographic illustrations are good, but the non-photographic ones are very unsatisfactory woodcuts after well-known photographs which surely might themselves have been used. Fig 16 is a case in which one of the least unpleasing mummies has been made hideous in the woodcut, which is drawn from an admirable photograph. We are sorry to see these ugly blemishes in a most useful book. H. R. HALL.

Our Bookshelf.

Allen's Commercial Organic Analysis. Edited by Samuel S. Sadtler, Dr. Elbert C. Lathrop, and C. Ainsworth Mitchell. Vol. 2: *Fixed Oils, Fats and Waxes, Special Characters and Methods, Butter Fat, Lard, Linseed Oil, Higher Fatty Acids, Soap, Glycerin, Wool-fat, Cloth Oils, Sterol Alcohols.* Fifth edition, revised and in part rewritten. Pp. ix + 807. (London: J. and A. Churchill, 1924.) 30s. net.

A PERIOD of fourteen years has elapsed since the publication of the equivalent volume in the last edition of Allen's "Commercial Organic Analysis." The reputation of this standard text-book is definitely upheld in the new volume. A comparison of the old and new shows that a thorough revision of data from the analytical investigation of fixed oils, fats, and waxes has been made, resulting in a considerable increase in the size of the book. A part of the increase is due to the fact that, while giving the latest and best methods, the older methods have in many cases been also intentionally retained. The section on the special characters and modes of examination of fats, oils, and waxes has been doubled in size and now covers nearly half the book, while some of the smaller sections show a fourfold expansion. Many subjects practically unknown in commercial analysis when the previous issue appeared (*e.g.* fermentation glycerin, vitamins, montan wax, etc.) have now their place in the new edition.

In the refined glycerin section, a reference is given

to the excellent "Ardeer Analytical Methods" book, but, so far as the reviewer is aware, this analytical process book is only available for private use in the Nobel Laboratories.

The book, which is printed in the United States, is excellently produced and the price reasonable compared with present-day standards. The increase in cost compared with the price of the former edition is less than proportional to the increase in size.

J. REILLY.

Evenings with the Stars. By Mary Procter. Pp. ix + 212 + 8 plates (London: Cassell and Co., Ltd., 1924.) 10*s.* 6*d.* net.

THIS work is not to be confused with the "Children's Book of the Heavens" by the same author. It is an entirely new work and is intended for amateur astronomers, and for those who wish to learn something about the constellations, both in their appearance in the sky, and in the wealth of legendary lore connected with them. Accordingly, the division is into twelve evenings or chapters, each dealing with a certain number of constellations near to one another in the sky, until the whole of the constellations visible in northern latitudes have been passed in review. The work is, in a spirit of filial piety, dedicated to the father of the author, the late distinguished astronomer, R. A. Proctor, "who taught me how to know and love the stars." From him she has inherited another gift, that of lucid and interesting description.

Each chapter is illustrated by a series of very clear and well-drawn original charts, by means of which the reader and student is safely piloted through the constellations. After a description of the constellation, the chief objects of interest are pointed out, with many aptly-chosen illustrative quotations from literary and legendary allusions to such objects. Appended to the twelve chapters is an interesting poem, the "Voices of the Suns," by the father of the author. There is also an excellent index, and in addition eight beautiful plates of nebulæ. The frontispiece in particular is a fine reproduction of the great cluster in Hercules, as photographed at the Dominion Astrophysical Observatory with the 72-inch reflector.

The book, too, is very well printed. Both for its astronomical and its literary excellence it can be highly recommended, and is deserving of a wide circulation. It is the work, too, of an expert.

A. L. C.

The Soil and its Management. By Prof. Merritt F. Miller. Pp. vi + 386. (Boston and London: Ginn and Co., 1924.) 7*s.* 6*d.* net.

PROF. MILLER'S book is designed for schools teaching vocational agriculture and for short-course students in agricultural colleges, and forms an admirable introductory course in agriculture. Little or no acquaintance with chemistry and other sciences is assumed. The author has succeeded notably in avoiding technicalities and has produced a most interesting and readable account of soils, soil fertility, and soil management without loss of clearness or accuracy.

The general arrangement is not very different from that adopted in most text-books dealing with the soil, but the treatment is unusually full for an elementary work, and the constant reference to farm practice and to observations and experiments which may readily be made on the farm and in the countryside is an attractive characteristic. At the end of each chapter there is a series of questions, together with skilfully selected practical exercises, both in the laboratory and in the field, and "home projects" for the benefit of the boy who lives on a farm. There are also references to more advanced books dealing with the various aspects of the subject. The numerous illustrations from photographs are another special feature: they are well reproduced and are very much to the point—particular mention may be made of the little series of pictures showing the crops in different rotations.

The author writes for American students and with American farming practice in view, and there is a good deal that is not directly applicable to conditions in Great Britain; but it is a work which all who have to do with the elementary teaching of agriculture will find most useful.

C. T. G.

Butterflies of India. By Chas. B. Antram. Pp. xvi + 226 (Calcutta and Simla: Thacker, Spink and Co., 1924.) 30 rupees.

THIS book is intended for the uninitiated, and its primary object is to illustrate all the Indian butterflies, except a few which are very closely alike. More than 500 species are dealt with, leaving the Lycænidæ and Hesperiidæ for treatment in a second volume. A few notes on the collection and preservation of specimens are given, and the remainder of the book is occupied with short and, so far as possible, non-technical specific descriptions. The characters given for three out of the four families are popularised, we think, to the extent of inefficiency, while the Nymphalidæ are not diagnosed at all. Generic keys or tables are dispensed with, no doubt on account of the difficulty of translating them into non-technical language. The reader, therefore, needs to compare his specimens with the illustrations and descriptions until he alights upon the correct species. After a little practice he will probably experience no great difficulties in doing so.

The book is well produced and will, no doubt, prove to be a useful popular guide for the many collectors of these insects scattered through India. On p. 38 there is a description of a new species of Parnassius from Tibet: it is hoped that the author will also publish a technical diagnosis of the insect, if he has not already done so, in some scientific periodical.

Lehrbuch der anorganischen Chemie. Von Karl A. Hofmann. Funfte Auflage. Pp. xiv + 761 + 7 Tafeln (Braunschweig: F. Vieweg und Sohn A.-G., 1924.) 17·50 gold marks.

PROF. HOFMANN'S text-book has been carefully revised and brought up-to-date. It gives a clear and fairly detailed account of the subject along recognised lines, including the rarer elements, and will be found useful by advanced students. As in most German text-books, a section on explosives is added. It gives an impression that German students make a special study of this subject.

Dutch Pendulum Observations in Submarines.

In the letter from Mr. Bowie on the subject of Dr. F. A Vening Meinesz's pendulum observations on board a submarine, which appeared in NATURE of December 27, 1924, p 930, there is a passage which seems to me to suggest a wrong idea of Dr Meinesz's method and thereby perhaps to engender doubts as to the possible accuracy of his results

Mr Bowie quotes the following pargraph from a paper which he presented at the Pan-Pacific Scientific Congress of 1920 "It is hoped that a satisfactory apparatus may be devised for determining the intensity of gravity at sea, using special vessels or commercial vessels There are several types of apparatus in existence, but no one of them gives results of sufficient accuracy for the study of isostasy The writer suggests that it may be possible to obtain a fair value of the intensity of gravity at sea by the use of the land apparatus properly mounted on a vessel. The apparatus would have to be swung in double gimbals and should be placed near the point of minimum translation resulting from the pitching and rolling of the vessel," and adds, "It was with great satisfaction that I read that Dr. Meinesz had accomplished the accurate determination of gravity at sea with the use of pendulums No doubt he arrived at the conclusion that the pendulum could be used independently of my suggestion in 1920"

The passage gives the impression that Dr. Meinesz's method consists of so mounting the apparatus as to reduce the disturbance due to the pitching and rolling of the vessel to a negligible quantity But this is not the method at all, and indeed one may reasonably doubt whether it would ever be possible to produce on board a ship a stillness at all comparable to that enjoyed by what the inhabitants doubtless consider the *terra firma* of the western part of Holland, yet in that region the instability of the ground is such that Dr Meinesz found it impossible to obtain any result by means of the pendulum apparatus used in the ordinary way, as the disturbance of the time of oscillation of the pendulum caused by the movements of the ground was far too great. The same difficulty has been met by other observers in places where the conditions are similar to those found in western Holland

To overcome this difficulty, Dr. Meinesz thought of the ingenious plan of swinging two pendulums simultaneously on the same stand. He showed by analysis that from observations of the times of swing of the two disturbed pendulums it was possible to deduce the time of swing of a hypothetical pendulum, the length of which is constant so long as those of the two real pendulums do not vary, and the time of swing of which is independent of the disturbances suffered by the real pendulums The two pendulums are swung in the same plane and on the same support; that is to say, their knife-edges are parallel and the surfaces on which they swing are rigidly connected. The idea of the method, to state it quite roughly, is that the two pendulums suffer equal but opposite disturbances, so that a mean undisturbed value is deducible

This method was found to give excellent results on the slightly unstable soil of Holland, and has also been found to give good results on a submarine where the instability, though much less than that of a ship floating on the surface, is nevertheless enormous compared with the least stable of the land stations.

I cannot believe that attempts to reduce the effects of a ship's movements by such devices as gimbals and the like would ever have been successful in freeing a pendulum, swinging by itself, from disturbances too great to be tolerable, but Dr. Meinesz introduces a new idea quite different from that of damping out the effects of the movements.

It is very desirable that the originality of Dr. Meinesz's method should be recognised and that he should have full credit as the sole inventor of a plan which seems to have solved the problem of the determination of gravity at sea.

Cambridge, December 30.

On a Connexion between the Spectra of Argon and Ionised Potassium.

THE quantitative relations between the spectra of argon and ionised potassium have been for some time a subject of investigation in the Amsterdam Laboratory The available observations are chiefly due to Schüllinger (*Wiener Sitz Ber* 118, 605, 1909), McLennan (Proc R.S, 100, 182, 1921), and Dik and Zeeman (*Proc Kon. Acad Amsterdam*, 1922, 1923). Schüllinger used a spark for the production of the K^+ spectrum, McLennan, as well as Dik and Zeeman, the electrodeless discharge. Dik and Zeeman got a rather pure K^+ spectrum, because with very intense discharges the arc lines were entirely suppressed, a result at variance with that of other observers The observations were obtained with a quartz spectrograph. The accuracy is, therefore, not sufficient for a scrutinising analysis, and observations with a grating spectrograph were projected

Prof Konen kindly informed us that in Bonn such measurements were already in hand, so that they were here postponed From the preliminary observations, Dik and Zeeman concluded that, in the spectrum of ionised potassium, constant differences of about 847 and 1696 were present, and this would point to a connexion with the red spectrum of argon (Rydberg). Afterwards the present authors (De Bruin and Zeeman, NATURE, Sept. 6, 1924, p. 352) investigated the blue spectrum of argon (accurate measurements of Eder and Valenta), and it appeared that a difference of about 846 here is also characteristic, as well as about 414 also found with the spectrum of K^+. Afterwards we found that Paulson (*Astr. Journ.*, 41, p. 75, 1915) had also hit upon the difference of about 846 in argon Recently, Dahmen (*Zeitschr. f. Phys.*, 29, 1924, p 264), of Bonn, has published measurements on ionised potassium, using a large grating, and potassium electrodes in an atmosphere of argon. In his experiments the arc lines are not absent, but his results are far more accurate.

From an examination of this new material, we have come to the conclusion that the difference of about 847 is not characteristic and probably cannot be maintained. The difference of about 1696 is present, a more accurate value being about 1712. Instead of the difference of about 414, we now find 418·2 for ionised potassium.

We have found some groups of regularly distributed lines exhibiting also regular distribution of intensities, a fact of some importance for the further analysis, because the intensities are closely connected with the inner quantum numbers. In the "quintets," the second component has the greater intensity, surpassing

always the first and third component. These groups of lines allow us to conclude that in Dahmen's observations some lines are absent which are present in Dik and Zeeman's tables

Some examples of "quintets" may be given here

Further details will be published by one of us (de B.) on another occasion.

T. L. DE BRUIN.
P. ZEEMAN.

Amsterdam, December 29.

The Ages of Peat Deposits.

DR. W. H. PEARSALL'S article on this subject in NATURE of December 6 refers to the absence of definite forest layers in the Pennine peat, in contrast to the peat with tree layers described by Lewis and others Dr. Pearsall appears to have overlooked the fact, however, that both the age and composition of mountain peat may differ considerably from that of marsh peat, in which tree layers are invariably found, and the presumption is that the Pennine peat to which he refers belongs to the former class The absence of tree layers in mountain peat is general throughout Ireland, whatever it may be elsewhere. This is due, not to the elevation at which it is formed, but to the stratum on which it rests, and which is invariably a surface soil, not always waterlogged, but deficient in lime and other alkaline bases, and on which the ordinary decomposition of humus is retarded or checked altogether. Tree stumps of Scots pine and birch, and more rarely oak, occur under the mountain peat up to elevations of 1500 feet to 2000 feet, and in situations where trees could not attain a similar size or rate of growth to-day.

Dr. Pearsall states that tree layers are not necessarily an indication of climatic change, and I agree with him. But they are undoubtedly an indication of change in the soil or peat water upon which the tree layers subsist, and also of the level at which the water table stood when they were growing. These root layers invariably show a decreasing size and rate of growth the higher they stand above the water table of the marsh which gave rise to the peat formation. The question is somewhat complicated by the fact that in most mountain districts, marsh and mountain peat are intermixed over wide areas, the mountain peat covering the higher and better drained surfaces, and the marsh peat the depressions or hollows which were originally small shallow lakes. The former never contains definite root layers, the latter root layers up to the level at which the sphagnum peat was formed, indicating a point at which sterility prevented all plant growth except mosses, stunted heather, and similar plants

So far as I am aware, few investigators distinguish between these two types of peat, and when tree layers are found in the shallow marsh peat of mountain districts, the fact is overlooked that they may be distinctly older than the mountain peat lying between them, and *under*, but *not in* which the tree stumps occur on the natural soil It is highly probable that the mountain peat corresponds in age to the Submerged Forest period, and also to the margins of the deeper and larger bogs of Ireland and Scotland. In these margins Scots pine and oak are usually found mixed, but in the deeper layers oak is absent

It is possible that considerable errors may arise by assuming that Scandinavian peat is of the same age as that of Ireland and Scotland Existing peat could not have been formed until the final retreat of the ice sheet, but probably began immediately after that retreat in the form of plant growth in the shallow lakes and marshes. Thousands of years may have separated the final retreat of the ice from the British Isles and its retreat from Southern Scandinavia, and in the interval peat has been forming wherever the conditions were suitable, irrespective of climate, although climate must have affected its rate of growth. That peat formation is going on to-day can be seen in many parts of the north and west wherever stagnant water accumulates, or soil surfaces are leaching out Neither the marsh peat in the one, nor the mountain peat in the other, is necessarily an indicator of climate, but the root layers in and under the marsh peat suggest that it is of a much greater age than the mountain peat so far as the lower layers are concerned The sphagnum peat is evidently a more recent growth, and reaches a more or less definite height in relation to the average diameter of the bog.

A. C FORBES.

Forestry Branch,
Dublin

IN NATURE for December 6, 1924, Dr. W. H. Pearsall directed attention to the results which have recently been achieved in work on the Pennine peat of Yorkshire; and discussed some of the problems of correlation which arise. Several of the points raised demand further comment.

After enumerating and discussing the validity of the conclusions reached by Lewis for the Scottish Peat Mosses, Dr. Pearsall says: "Samuelsson has

reinvestigated the Scottish deposits and his main conclusions agree with those of Lewis." This statement might almost be described as a travesty of the facts. Samuelsson (Bull Geol. Inst Upsala, Vol. X. pp. 197-260) does indeed confirm the general *succession* established by Lewis; but even in this there is not entire agreement. (See, for example, p 222) Lewis's main conclusions are surely contained in his correlation of the peat succession with the later glacial and interglacial periods of the system devised by James Geikie, and with this correlation Samuelsson disagrees. In the early part of a critical discussion (see especially pp. 217-226) he says: "Lewis has started from Geikie's point of view and endeavoured to bring his results into accordance with Geikie's opinion as much as possible But by holding one-sidedly on to the correctness of Geikie's classification of the late quaternary history of Scotland, Lewis has been led to some conclusions that are certainly wrong."

The arguments of Geikie and Lewis for the interglacial age of part of the Scottish peat may be summarised thus:

(1) A submerged forest (with present day flora) underlies the carse lands of the Forth and Tay.
(2) These carse lands rise inland and pass into the gravels of the 45-50 ft Raised Beach
(3) Moraines have been seen resting on this beach.

Therefore, the Submerged Forest is earlier than the glaciation represented by the moraines. The Submerged Forest is taken to be represented in the Scottish peat by the Lower Forestian, the glaciation by the 2nd Arctic Bed (Lower Turbarian), a subsequent emergence by the Upper Forestian, and a further submergence (25 foot Beach) by the Upper Turbarian.

This beautifully sequential argument is utterly destroyed by the following considerations:

(1) There is no contemporaneity between the carse lands of the Forth and Tay and the gravels of the 45-50 ft. beach.
(2) There is no independent evidence for the emergence which is supposed to be represented by the Upper Forestian; and, in any case, Samuelsson has pointed out that no such emergence is necessary.

Not content with quoting results based on a miscorrelation, Dr Pearsall states: "Now along the Scottish coasts, the submerged forests are replaced by the 40-50 ft. beaches, also of Neolithic date. ." This is confusion worse confounded indeed! It is not that the results and conclusions of later workers are hidden away in obscure and widely scattered journals On the contrary, in Wright's "Quaternary Ice Age" (chap xvi.) there is a delightfully clear, concise and well-written presentation of the evidence bearing on the raised beaches and submerged forests of the British Isles Here it is plainly stated that there exists in Scotland a group of raised beaches, ranging from the 100 ft. to the 40 ft. level, which are in part contemporaneous with the existence of large glaciers, and that these are separated from the 25 ft. raised beach of Scotland, Northern England and Ireland, by a period of emergence in which the submerged forests grew. It is to this ("25 ft.") period of submergence that the carse clays of the Forth and Tay belong, and these clays, as well as the associated beach gravels, have been proved, in all cases where the relation can be observed, to overlie the Submerged Forest.

The 25 ft. beach contains Campignien implements exactly similar in type to those which are found associated with the kitchen middens of the maximum of the Littorina depression in Scandinavia; and, in Scandinavia, this Campignien industry is associated with pigmy flints of Tardenoisien type. This evidence appears to contradict Clement Reid's assignation of a Neolithic date to the submerged forest, which is quoted by Dr. Pearsall. In this connexion, however, it must be remembered that Clement Reid was not speaking of the submerged forests of Scotland and Northern England, and also that the submerged forests increase in number and in depth outwards from Scotland. The uppermost submerged forest of Southern England and Wales appears to be of Neolithic or even Bronze Age, but it is possible that the Scottish submerged forest, of which the pre-Tardenoisien age is undoubted, represents the lowest submerged forest of the areas further south.

Now Dr. Pearsall tentatively correlates the Submerged Forest with the birch forest at the base of the Pennine peat, and suggests that its destruction coincided with the colder climate assumed for the Lower Turbarian. Dr Woodhead, however (*Journ. Bot*, Oct. 1924, p. 303), does not assume any increasing cold to account for the destruction of this forest. Further, if the Pennine forest lies above sand containing relics of a Tardenoisien industry, and the Submerged Forest lies below gravels of the same date, the two cannot be contemporaneous.

It is, of course, very desirable that correlation should be attempted, but, until Dr Pearsall can build on better and on sounder foundations than he has done, it seems a pity that the very beautiful and precise work done by Mr. Holmes, Mr. Buckley and Dr Woodhead should be obscured by such speculations

LAURANCE H. TONKS.

Manchester, December 12, 1924.

MR. TONKS raises some interesting points to which further reference seems to me desirable, in regard to my article on the ages of peat deposits That article refers to the peat horizons recognised by Lewis in Scotland and uses the names which Lewis adopted. It points out that these "roughly correspond" to Geikie's well-known climatic periods. Mr. Tonks appears to assume from this that I have accepted and argued from the whole of the implications of the Lewis-Geikie system. Nothing could be further from the truth. Mr. Tonks then apparently accuses me of declaring that Samuelsson has agreed with these implications. It is, in fact, evident from the paragraph in which my reference to Samuelsson occurs—that the points of agreement between Samuelsson and Lewis to which I refer are the nature of the Scotch peat succession, its widespread character and its possible relation to climate. My opinion that these are the main conclusions to be drawn from the work of Lewis remains unshaken. The article further refers to the "submerged forests round the English coasts" and not to those known in Scotland, to which Mr. Tonks refers at length. There appears to be no clear evidence that the English and Scotch submerged forests are of the same age although the suggestion Mr. Tonks makes is quite possible. Much of Mr. Tonks's letter is thus based on misinterpretations and misunderstandings.

One of the objects of the article was to indicate, so far as possible, that if one attempts to correlate the results of the British and Scandinavian peat investigations, then the results throw considerable doubt on what may be termed the climatic hypothesis of peat stratification. This result is actually obtained whether the age of the Scotch peats is estimated through the 40-50 ft. beaches, a doubtful method as Mr. Tonks shows, or through the 25 ft. beaches. In the latter

case, according to Lewis, the mosses in Southern Scotland lying on the 25 ft. beaches have a basal layer of shrub remains (largely birch) above which are peat layers chiefly composed of Eriophorum. This stratification agrees with that of the upper layers of the older mosses further inland. The wood layer *may* thus approximate to that of Lewis's Upper Forest layer, and since the 25 ft beaches are about Campignien age, the Upper Forest would be approximately Neolithic. On the climatic hypothesis, this might be held to suggest that the Neolithic period was relatively warm and dry in Scotland—agreeing on the whole with the Scandinavian conclusion Yet in the Pennines this period appears to have been one of forest destruction and peat development, which would, on the climatic hypothesis, require cold and moist conditions.

The whole point of these attempted correlations, so far as I am concerned, is that on whatever they are based, they result in throwing doubt on the hypothesis that peat stratification is, in Britain, an indication of climatic change The method employed in the original article results in the correlation of Lower Turbarian (presumably cold and moist) with the destruction of the Pennine Forest While this is better so far as Britain is concerned, it means on the climatic hypothesis that in Neolithic Britain conditions tended to be cold and moist, while in Scandinavia they were relatively warm and dry. The point of my article as expressed in the last two paragraphs remains just as clear if the Scottish peats are wholly ignored They represent, however, the chief British evidence for the climatic theory of peat succession, and hence the attempt was made to include them, though admittedly nothing but the establishment of cultural horizons can give an adequate basis for this correlation

W. H PEARSALL

Acid-base Titrations and Equilibria of Weak Bases and Acids.

IT has been supposed in the past that substances with feebly acidic or basic properties, say with K_a or K_b less than $2{\cdot}5 \times 10^{-9}$ in the case of N/20 dilution, are incapable [1] of estimation by acid-base titrations. I have recently succeeded in elaborating a technique by which this object can be attained: the main principles involved are set out below.

The titration of strong acids or bases in the presence of indicators depends on the steep (and maximal) gradient in the degree of acidity (hydrogen ion concentration, P_H) at the "end-point" in the neutralisation. Thus, with a fairly strong base the P_H during a titration is governed by the well-known mass-law approximation,[2]

$$p_{Kw} - p_H = \log \frac{1}{[\dot{O}H^-]} = \log \frac{1}{K_b} + \log \frac{[\text{Acid added}]}{[\text{Base remaining unneutralised}]}, \quad (1)$$

from which can be deduced the indicator with most suitable transition zone for the titration. An analogous equation holds for the titration of fairly strong acids.

Equation (1) rests on the assumption that all the acid added to the weak base goes to form a completely dissociated salt and that the free base is itself non-ionised. The first assumption is no longer true with a very weak base having a dissociation constant commensurate with that of water: a highly acid solution is formed, a large fraction of the added acid is uncombined with the base, and the effect of the acid on the solute is masked by its effect on the solvent, no end-point being shown when P_H is plotted against added acid. This difficulty has been overcome by a formula and method of approach already applied by the writer to amino-acids and polypeptides [3] From each value of "Acid added" is subtracted the amount present in the free state, which can be calculated from the equation

$$[H^+] = a[\text{free HCl}], \quad . \quad . \quad . \quad (2)$$

where a is known and $[H^+]$ is the quantity determined experimentally, and it is found that the formula so modified becomes strictly applicable to the very feeblest bases, and the corresponding modified formula equally applicable to acids. The *modus operandi* of the technique is to determine the volume of standard soda or hydrochloric acid required to titrate the solute over a given P_H range or to a given P_H end-point: for any given K_a or K_b value this is directly proportional to the amount of solute present With the simplified apparatus now available, such as the Cambridge Instrument Co.'s portable outfit and Mr S. W. Cole's hydrogen electrode, a complete electrometric P_H determination can be carried out within the space of several minutes

The theory has now been tested in detail in relation to some thirty acidic and basic groups The accuracy obtainable is found to be of the same order as that of an ordinary acid-base titration by the old-fashioned method. Thus the very feeble second basic group in arginine ($K = 1{\cdot}2 \times 10^{-12}$) may be estimated with an accuracy of at least 1 part in 100 in, say, M/20 solutions, while the P_H during the course of a titration may be predicted to within 0·02 P_H units, that is, with an accuracy comparable with that attaching to the experimental reading With mixtures of acids or bases of different strengths the corrected amounts of alkali (or hydrochloric acid) required to titrate over a given P_H range is the sum of the amounts for each acidic or basic group

Utilising this fact, I have been able to resolve a compound titration curve into its various components and estimate each of a number of acids and bases or ampholytes present simultaneously in a mixture, even when the respective K_a and K_b values are sufficiently close to cause partial overlapping of the individual titration curves In order to estimate a given substance, it is not essential to know the exact K_a or K_b values when once its P_H combination curve has been determined, and on this basis I have been able to make accurate determinations of proteins in solution. Details will shortly be published (Proc Roy. Soc., B.) Other applications have included investigations of the molecular weight and chemical constitution and dissociation constants of several bodies of biochemical interest, and the detection of chemical changes (*e.g.* the disproof of the theory of acid or base addition at peptide linkage in dipeptides) particularly those occurring during denaturation and enzyme hydrolysis.

An experimentally determined "correction for blank" has previously been arbitrarily used by Tague [4] for the action of soda on amino-acids, but without reference to the titration theory, mass law equation, K_a and K_b values, or prediction of titration curves.

In deducing differential expressions for buffer value, Van Slyke [5] (1922) independently made use of a formula which is similar to the present writer's, but in which no account is taken of the incomplete dissociation of the titrant. The effect of the latter on the accuracy of the formulæ is evident from the

[1] J. Chem. Soc., vol. 119, pp. 140, 156 (1921).
[2] Biochem. Z., vol. 78, p. 122 (1917).
[3] Proc. Roy Soc., B, vol. 95, pp. 440-484, 500-522 (1923-4), J. Chem. Soc., vol. 123, pp. 3294-3303 (1923).
[4] J. Amer. Chem. Soc., vol. 42, p. 173 (1920)
[5] J. Biol Chem., vol. 52, p. 525 (1922)

following values for the second basic dissociation "constant" of arginine calculated from the experimental P_H values.

P_H	$p_{K_2'}$ Harris's Formula.	Van Slyke's Formula.
3·14	11·90	11·89
2·52	11·90	11·88
1·84	11·90	11·75

It was shown[8] that for amino-acids, results sufficiently accurate for most purposes could be obtained if α in equation (2) were taken as 0·9 when concentrations less than N/10 were dealt with. As recently emphasised by Cohn, P_H determined electrically is a measure of hydrogen ion "activity" rather than "concentration". I have obtained results sufficiently accurate for analytical purposes by taking for α Noyes and McInnes'[8] figures for the activity of KCl of the same concentration as that of the total HCl (titrant) added at each stage in the titration. Similar conclusions have been reached in titrating weakly acidic groups with soda. For highly accurate theoretical purposes I have calculated values of α for use in the presence of weakly basic or acidic groups of amino-acids from Sorensen's very careful P_H determinations of glycine—HCl and —NaOH buffers. My theoretical investigations relate mainly the one acidic and one basic group in glycine, and the one acidic and two basic groups in arginine: it is intended to publish a detailed report in due course.

The Ages and Masses of the Stars.

IN his article on "The Ages and Masses of the Stars" (NATURE, December 6, 1924), Dr. J. H. Jeans, to account for the source of stellar radiation, considers the possibility of positive and negative charges falling together, annihilating each other, and passing away "in a blaze of glory," thus setting free enormous amounts of "sub-electronic" energy. Proceeding, he says, "Nothing in the suggestion appears to conflict with modern atomic physics" and gives his reasons.

This may be very true, since we have nothing to disprove such a theory; but to make an assumption of such a fundamental nature, and, as it seems to me, on insufficient grounds, is rather disconcerting to a conservative mind. It requires some imagination to think of an electron and a nucleus, the properties of which are so vastly different, as "cancelling" one another.

The author's one strong argument in favour of his theory is based on the loss of the mass of stars as obtained by Eddington (cf. NATURE, May 31, 1924). In support of his theory of the annihilation of matter, Jeans makes the highly contestable statement, that "we know of no normal process by which mass can escape except by radiation, whence we conclude that the diminution of mass is the equivalent of the energy radiated away." Objection to this can immediately be raised on the ground that we have direct evidence of a stellar body losing mass, in the case of the tails of comets. Moreover, it has been shown by Gouy (*Comptes rendus*, 157, 186, 1913) and Page (*Astrophys. Journal*, vol. lii. No. 2, September 1920) that, in the case of an atomic vibrator, the radiation pressure may very well exceed the gravitational attraction on the surface of our sun. It is, therefore, quite imaginable that the sun is losing mass from its surface in this way all the time. In a greater degree would this be the case on hotter stars, even though much more massive than the sun.

On the other hand, if we reject Jeans's hypothesis, we rob him of his nearly unlimited supply of energy; but could this not, in a small way, be compensated for by attributing to the stars a high degree of radioactivity, this source of energy, I take it, not having been included by the author in his computation of the "super-electronic" energy of the stars?

T. SCHUMANN.

Sloane Laboratory, Yale University,
New Haven, Conn., U.S.A.,
December 17.

THE merit I am inclined to claim for my hypothesis of sub-electronic energy is that this one simple hypothesis clears away a whole tangle of astronomical difficulties. The hypothesis may strike the physicist as unproved and unprovable, as it certainly is, but I think the following considerations will show that it ought not to be dismissed as fantastic.

A gram of every substance (except hydrogen) contains 3×10^{23} negative electrons and a corresponding quantity of positive electricity. Each gram of the sun's mass radiates 60 million ergs per annum, so that if sub-electronic energy is not drawn upon, each of these electric charges must fall through an average potential difference of 0·0012 volts. The fall for one year does not look big, but radiation for 10^9 years requires an average fall of 120,000 volts, representing a fall from infinity to only 10^{-13} cm. from a charge $\pm e$. The figure of 10^9 years is the absolute minimum that can be considered; evidence from the orbits of binaries and from the approximate equipartition of energy in stellar velocities calls rather insistently for 10^{13} or even 10^{14} years. Also giant stars radiate anything up to a thousand times as much per unit mass as our sun. It would be possible to find tolerably good reasons for replacing the above figure of 120,000 volts by 12×10^9 volts, and 10^{-13} cm. by 10^{-17} cm. If we have to contemplate positive and negative charges getting as near to one another as this, it would seem that they might as well go a bit farther. To my mind it is easier to imagine a few charges stumbling into one another than to imagine a whole lot falling through these enormous potential differences and then stopping.

Radioactive energy and energy of nuclear rearrangement can, of course, be covered by an argument of the same general type, except that we have to picture charges of the same sign starting at these infinitesimal distances from one another. There is nothing impossible in it, but neither, I claim, is there in the hypothesis of mutual annihilation. The inadequacy of the highest degree of radioactivity known to us has been pointed out by Lindemann and others, but it has to be conceded that substances of far higher radioactivity may exist in the stars.

A comet's tail can lose mass, and this loss of mass may be permanent, because the comet's own gravitational field is slight in comparison with the general field of the sun, but the conditions are different for a body of stellar mass. So soon as a particle expelled by radiation pressure loses or changes its period of vibration, it will fall back into the star. A cosmogony based on the conceptions suggested by Mr. Schumann would seem to me to create more difficulties than it removes, but others may think differently. Mr. Schumann's cosmogony would certainly fit in well with Prof. Lindemann's theory of the nature of spiral nebulæ.

London Fog of January 11-12, 1925.

THE accompanying curve (Fig 1) indicates the variation in the quantity of suspended impurity in the air of Westminster during the recent fog. There was nothing very abnormal until the night of Saturday, January 10, when the suspended impurity, instead of gradually falling in the afternoon as it usually does, commenced to rise at about 5 P M , reaching about 2 milligrams per cubic metre by 9 P.M This level of impurity was maintained until midnight, when the normal fall occurred to a minimum of less than 0 5 milligram per cubic metre at 5-7 o'clock on Sunday morning. After this the impurity rose rapidly until it passed beyond the scale of the recording instrument at 3 o'clock on Sunday afternoon It remained at this abnormally high level, which was more than 6 5 milligrams per cubic metre—probably approaching 10—until 7 P.M , when a gradual fall commenced, which was maintained fairly steadily until 5 o'clock on Monday morning, when the impurity was a little more than 0·5 milligram The same rapid increase in impurity again began on Monday morning about 7 A M., reaching a maximum of a little less than 4 milligrams per cubic metre at noon This was maintained until 3 P M , when there was a rapid fall until 6 P M.

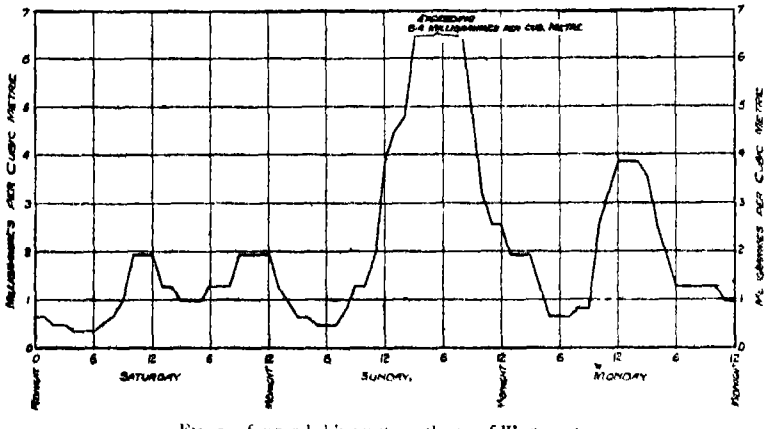

FIG. 1 Suspended impurity in the air of Westminster, Saturday, January 10 - Monday, January 12

There were one or two interesting points noticeable in this fog A dust record at 11 o'clock on Monday morning showed a reading of nearly 30,000 particles per c c. Unfortunately, no dust counts were available for the maximum period on Sunday, but there is usually a relation between the impurity recorded automatically by filtration and the dust count, indicating that about 8000 to 10,000 particles per cubic centimetre correspond to 1 milligram per cubic metre. On this basis there must have been something approaching 100,000 particles per cubic centimetre during the height of the fog on Sunday

Dust records taken 11 miles south-west of London, at Cheam, on Sunday afternoon, gave 15,000 to 16,000 soot particles per cubic centimetre, varying in diameter from 1·5 microns down, the average being about 0·7 to 0·8 micron. There were a few spherical particles and also a few drops of yellow oily-looking liquid, doubtless tar.

A dense record from 1000 cubic centimetres of air showed a number of dried-up stream beds blown out from the sides of the dust trace and formed by the water particles of the fog, and in the heads of these dried-up streams a large quantity of crystalline matter, in the form of skeletal crystals. The record itself was a thick, black line.

A microscope slide exposed from 4·37 to 4·55 P.M. and afterwards examined showed an extraordinarily rapid rate of settlement, the number of particles settling per square centimetre per minute at that time amounting to 80,000

A cover glass exposed from 5·4 to 5 24 P.M. in the same way showed a deposit at the rate of 75,000 particles per square centimetre per minute These particles were not water drops but solid matter and varied in size from about 1·5 microns down. There were a few small spheres Most of the particles were in the form of aggregates, but very few showed any indication of having been held in the water drops There were a few scattered particles, apparently crystalline in structure, and about 1·5 microns in diameter, which formed the centre of groups of smaller particles, suggesting the dried-up site of the impact of a drop The formation of aggregates and the entire absence of wind may be the cause of the exceptional rate of settlement, as the number settling was much greater than would be accounted for by the normal deposit of particles of a diameter of about 1 micron

On Monday morning the leaves and twigs in the hedges were covered with thick hoar frost which was brown in appearance A slide left out overnight was covered with ice which, when melted, gave a pool of black water, the roads were coated with a dark scum which, on the pools of water, showed as an iridescent oily-looking film It is very obvious that we were getting the London smoke in almost as great quantity as in a moderate London fog.

It would be of interest if any readers of NATURE living between south and west of London observed the phenomenon of this black deposit or discoloured ice crystals.

The Discovery of Argon.

SIR J J. THOMSON'S reference to the discovery of argon, in his review in NATURE of December 6 of the life of Lord Rayleigh, will be read by chemists with surprise but without conviction, and though his comments upon chemistry must be received with the respect due to a late president of the Royal Society, they must also give rise to a certain amount of amusement. It is, however, with positive pain that many chemists have read Prof Armstrong's letter upon this subject published in NATURE of January 10. What does he mean by " behind the scenes " and " Ramsay and his ways " ?

As to the award of the medal, Prof. Armstrong omits to refer to Lord Rayleigh's speech on receiving it. This is printed in the Proceedings of the Chemical Society, from which I quote as follows " Lord Rayleigh, on receiving the medal, said that, in returning his thanks to the Society, he was somewhat embarrassed, because he felt that there ought to be another standing by his side . . . the credit for it must be

shared equally between Professor Ramsay and himself. In some quarters there had been a tendency to represent that antagonism existed between chemists and physicists in the matter, though such a thought had never entered his head. Professor Ramsay was a chemist by profession, while he himself had dabbled in chemistry from an early age, and had followed its development with very keen interest."

I returned from France to Ramsay's laboratory as an assistant in the autumn of 1894, and the first words he said to me, after shaking hands, were, "Well, it is a new gas." From April 1895 I was daily associated with him for years, and I have heard the early history of the discovery told many times. This I know for a fact: when Ramsay communicated his preliminary results to Lord Rayleigh, he placed them at his disposal, but Lord Rayleigh was equally willing to allow Ramsay to go forward with the work alone. I do not believe that either of these two great men ever felt the slightest regret that the discovery was shared. As a matter of fact, if neither of them had discovered argon their reputation would be scarcely less enduring.

Even during the preliminary stage, there were attempts to disturb the friendly relations between the two discoverers. A well-known chemist called on Ramsay, and after being shown everything, after the manner of Ramsay, went home and wrote to Lord Rayleigh, telling him that he must place no reliance on Ramsay's work Lord Rayleigh sent the letter on to Ramsay, with a brief comment, which Ramsay passed on to the author Later the "Suum cuique" letters in the *Chemical News* showed chemists that there were people in their ranks capable of the most unworthy actions

However, Ramsay, when alive, knew well when to meet and reply to criticism, and when to "Let them say" Ramsay, dead, will not suffer from attacks directed from "behind the scenes", but it may be hoped that the pages of NATURE will not be open to those who would discredit him in this manner

The Possibility of reproducing the Electrical Conditions of the Nitrogen Afterglow.

In a paper by Johnson and myself (Proc. Roy. Soc. A, vol 106, p 200) on the effect of argon on certain spectra, attention was directed to structural modifications induced in the CH band, λ4315, and in the CN bands, these being similar to changes observed by Strutt and Fowler (Proc. Roy Soc A, vol 86, p. 116), when these spectra were stimulated in the afterglow of nitrogen In a recent paper by Johnson (*Phil. Mag* vi, vol 48, p 1069) further evidence has been adduced for the similarity of the electrical conditions obtained in the afterglow to those existing when mild uncondensed discharges are passed through high-pressure argon In particular, an energy displacement in the first positive band spectrum, as developed in a tube containing a little nitrogen in the presence of high-pressure argon, was regarded as the analogue of the selection of three of the more refrangible heads in the several groups constituting the visible spectrum of the afterglow. The energy displacement was related quantitatively to the percentage of nitrogen in the nitrogen-argon mixture If the analogy can be sustained, it should follow that the intensity maximum in the several groups of the afterglow spectrum will be displaced a little towards the violet end as the afterglow is dying away (that is, as the percentage of activated molecules diminishes).

To test this, the spectrum of the afterglow has been photographed through a neutral wedge at two points about 7 inches apart in a glass tube, through which a stream of glowing nitrogen was pumped. Owing to the comparatively small light gathering power of the spectrograph, photographic exposures of 16 and 40 hours respectively were necessary, and even then the intensity was insufficient to permit of quantitative measurement of the plates. A close comparison, however, indicated no pronounced energy displacement.

Attempts have also been made to reproduce the β-group of the afterglow spectrum from discharge tubes containing nitrogen and argon, but no positive results have been obtained. Incidentally, I have examined the spectrum of the light from discharges through ammonia in high-pressure argon, in the hope of obtaining the spectrum of the afterglow when atomic nitrogen (arising from the destruction of the NH_3 molecule) returned to the molecular state. There was no evidence, however, of either the characteristic α or β groups occurring.

I have also excited the band spectrum of iodine in the presence of high-pressure argon, but did not observe the relative intensity changes which Strutt and Fowler record as characteristic of the development in the afterglow

It would appear, therefore, that while there remain several points of resemblance between the electrical conditions of the afterglow and those existing when a mild discharge is passed through high-pressure argon, there are many specific effects of the former which are incapable of reproduction in the latter case

Science and the Community.

THE article under this title in the issue of NATURE of January 3 refers to the small part played by scientific men in public affairs and in business life. I think that the explanation of this is simple. One man has a fixed amount of daily energy. If he makes a great effort in one direction his effort in another direction is correspondingly weak; and so, in general, one man cannot excel in more than one direction.

Now a successful business man, or, even more so, a politician, owes his success almost entirely to his powers of divining the wishes and thoughts of that strange creature—man. A man of science, however, is dealing with an inanimate world which cannot be influenced by tact, persuasive powers, or individuality. Consequently, in general, those personal qualities and mental characteristics which lead a man to success in business have no relationship at all to those which lead to success in scientific work. In fact, the inexactitudes and tactful misrepresentations characteristic of the business and political world are excessively distasteful to a man trained in the clear honesty and rigour of scientific thought, and put him at a positive disadvantage compared to his commercial fellow-man when engaged upon delicate negotiations of any sort.

In general, a man who has worked for years studying physics and higher mathematics will be much less tactful and much less persuasive, and will probably be a worse judge of character, than a man who has spent an equally strenuous number of years in persuading people to buy something which they do not really need. GEOFFREY MARTIN.

The Propagation of Wireless Waves of Short Wave-length round the World.

By Dr J A. FLEMING, F.R.S.

QUITE the most important of the pronouncements of the past year in connexion with wireless telegraphy were the two addresses given by Senatore Marconi to the Royal Society of Arts, London, in July and December, and also a paper by Sir Joseph Larmor, in NATURE of November 1, and the *Philosophical Magazine* for December last, on the theory of wireless transmission round the world Senatore Marconi gave details in July of his remarkable achievements with electric waves of relatively short wave-length, and in December of his discovery that waves of only 30 metres in length, or about 100 ft, can be used for reliable communication by day as well as by night over any distance, even to the antipodes, although entire continents and mountain ranges intervene (see NATURE, September 6, p. 359, and December 27, p 939) In this most important advance, he has certainly priority of achievement, as he had in 1901, in long-wave transmission across the Atlantic. When in 1902 Senatore Marconi discovered the great difference in range between day and night transmission with long waves across the Atlantic, it at once became clear that wireless transmission involved not only the ether of space round the earth, but also that the atmosphere itself, and especially, its state as regards illumination by sunlight, had a great deal to do with the matter.

In the years that followed, radio engineers came to the conclusion that the best prescription for achieving regular commercial radiotelegraphy at all times of day and night over long world-distances was by increasing the wave-length and power. Hence between 1902 and 1922 the demand for long distance radiotelegraphy involved the erection of large high-power all-round stations with great aerials sending out electric waves 30,000 to 60,000 ft. in wave-length, and using power from 500 to 1500 horse-power or more. The latest example is the 1000-kilowatt British Government radio station now being erected at Rugby.

The inhabited land area of the world being chiefly confined to one-half of the terrestrial globe, and the useful long wave-lengths being included within somewhat narrow limits, it is clear there is not an unlimited possibility of putting up all-round super-power radio stations without risk of interference.

Accordingly, so far back as 1916, Senatore Marconi began to consider the alternative of exploring the utility of the other extremity of the wireless spectrum or gamut of wave-lengths, and using waves more nearly 100 to 300 ft in wave-length projected as a beam by skeleton parabolic mirrors of vertical wires. It was well understood that when using such mirrors, the wave-length employed must be less than the aperture and height of the mirror, and constructive difficulties placed a limit on the mirror dimensions. Hence for beam projection short wave-lengths were essential. In 1916, experiments were conducted by Marconi in Italy with such short-wave beam radiotelegraphy for war purposes; and later in England, with the able assistance of Mr. C. S. Franklin, important results were obtained in radiotelephony by 15-metre waves between London and Birmingham. The achievements between 1916 and 1922 described in published papers by Senatore Marconi and Mr. Franklin in 1922, amply demonstrated the practical value of these short waves of 100-metre wave-length or less. In 1923, a series of tests by Marconi and his assistants on his yacht over long world-distances showed that communication could be established by these waves from Poldhu to Australia, but that the 100-metre wave had a markedly greater range by night than by day

In October of 1924, Marconi discovered that the daylight range increased very rapidly as the wave-length was reduced from 100 to 32 metres, or say from 300 to 100 ft , and that perfect communication could be established for all hours of the day and night between England and Australia by the 32-metre wave when using only 10 or 12 kilowatts (say 15 h.p.) in the transmitter

Apart altogether from the immense practical importance of this discovery, it raises scientific questions of high interest as to the mechanism by which these waves travel round the world It is now quite clear that normal wave diffraction is not sufficient The signal strengths at large world-distances are thousands of times greater than they could be by mere diffraction. It is generally agreed that the effect must be due in some way to ionisation of the high-level atmosphere, which descends to a lower level during the day-time. Although many theories have been put forward, the important paper by Sir Joseph Larmor, above mentioned, throws fresh light on the subject. When an electric wave passes through ionised air it sets the ions in vibration If the ions collide at once with gas molecules, energy is dissipated and the wave is weakened

If the mean free path of the ion is long (say 10 times) compared with the distance the ion is moved by the wave in the periodic time of the wave, then there will not be much dissipation of energy but the effective dielectric constant of the medium will be reduced and the wave velocity increased.

Larmor shows that at a certain height in the atmosphere, there is a region in which this accelerated and slightly dissipated wave energy can travel, and that a comparatively small ionic density will be effective. His equations show that the increase in wave speed depends on the ionic density and the square of the wave-length, and the modulus of absorption of the wave energy on the product of the ionic density and wave-length.

The increase in speed of the upper part of the wave front causes the wireless ray to curve round the earth, and Larmor specifies the conditions which must be fulfilled for the required curvature to be produced.

It appears, then, that for a given ionic density the long waves are more absorbed than the short, but the long waves have more energy at starting. Each wireless ray has its own proper path in the ionised air in travelling from the transmitter to any receiver. The shorter waves travel at a higher level in the atmosphere where the ionic density is greater and more constant, and this compensates for the smaller wave-length in giving the required ray curvature and makes them less affected by day and night variations. The

longer waves travel chiefly in a region in which the ionic density varies very much between day and night and are thus less absorbed by night.

In a general way, therefore, the theory fits in with facts, but there are an immense number of well-known wireless wave effects which will require consideration and discussion before we can say we can account for them all on any theory Meanwhile, the practical consequences of the discovery of the properties of this 32-metre wave are very great

Is there, for example, any justification for creating new high-power all-round radio stations by which the communication is so to speak, bellowed over the world on 20,000-metre waves, when on the beam system perhaps a dozen stations could be erected for the same capital and annual working cost, which would whisper their message on 32-metre waves along limited paths, taking up much less room in the ether? Time, and perhaps expensive experience, will show whether the all-round high-power station is necessary. In any event, the short-wave system has the enormous advantage that the receiving appliances used in connexion with it are vastly more immune from atmospheric disturbances and render all-day and all-night intercommunication possible over long distances, even up to the antipodes.

The Oldest Fossil Fishes.

By Sir ARTHUR SMITH WOODWARD, F.R.S.

IT has long been known that the fishes of the Downtonian age--the earliest fishes of which we have any real knowledge—are very different from those which appeared in later times and persist in part to the present day. Prof Johan Kiær, of the University of Christiania, discovered fossil fishes in the rocks of this period in southern Norway a few years ago, and the first part of his memoir describing them has recently been issued [1] Prof Kiær's remarkable specimens add greatly to our knowledge of these fishes, and some of his conclusions are so unexpected that they are of extreme interest to both zoologists and geologists

FIG. 1.—*Aceraspis robustus*, Kiær Neatly complete specimen, nat size The foremost part of the head is incomplete. From "The Downtonian Fauna of Norway"

It appears that the Downtonian rocks of the Christiania region closely resemble those of Great Britain, and similarly contain the fishes in association with crustaceans and eurypterids in a good state of preservation They are shallow water deposits, with frequent traces of ripple marks and sun cracks, and Prof. Kiær thinks they must have been formed in freshwater lakes on flood-plains Some of the fishes are familiar, such as the beautiful Cephalaspidian reproduced in Fig. 1, which differs little from Cephalaspis itself except in having two dorsal fins instead of the single one. All, indeed, belong to known groups, and all are as usual small, none being more than two decimetres in length. The most striking novelties are referable to the Anaspida—laterally compressed fusiform fishes which were first described by the late Dr. R. H. Traquair from the Downtonian rocks of southern Scotland—and Prof. Kiær begins by devoting attention to the three new genera which he finds among these

In the original Scottish specimens, Dr. Traquair was unable to make out any definite features in the head, and until he obtained examples with the heterocercal (or primitive unequal-lobed) tail, he felt uncertain as to which were the dorsal and ventral borders respectively. In the new Norwegian specimens Prof Kiær has been more fortunate in finding both the head and the tail well preserved, and it now appears that the Anaspida differ from all other known heterocercal fishes in having the tapering end of the body bent downwards instead of upwards (see Fig. 2). Dr. Traquair indeed described all his specimens upside down. We have for the first time among fishes a form of tail which is known among the extinct marine reptiles, the ichthyosaurs, mosasaurs, and certain Jurassic crocodiles. Prof Kiær, following Schmalhausen, supposes that this arrangement is correlated with the position of the centre of gravity of the fish.

The roof of the skull, which led to the discovery of the anomaly in the tail, is also very interesting. So far as it affords a clue to the underlying soft parts, it agrees with the cranial roof in the contemporary and allied cephalaspidians. As shown in Prof. Kiær's outline restorations (Fig. 3), the large orbits are distinct, not far apart, and each is surrounded by a hard rim. Between them is a plate pierced by a perforation doubtless for the pineal body; and immediately in front of this is a larger median perforation which may

[1] The Downtonian Fauna of Norway. I Anaspida, with a Geological Introduction By Johan Kiær *Vidensk Skrift. I, Mat.-naturv. Kl.* 1924, No. 6. Kristiania, 1924

be rightly interpreted as an unpaired narial opening. The small dermal plates are symmetrically arranged and nearly on the same pattern in the three genera, but there is a tendency towards fusion into fewer and larger plates as shown in the three successive sketches *a*, *b*, *c*. In side view (Fig. 2) the cleft of the mouth is now seen for the first time in Anaspida, and it is bordered with large plates, at least in the genus here restored. In upper view (Fig. 3) the cranial dermal plates pass gradually backwards into the scales of the body, but on the side (Fig. 2) the limit of the head region is marked by a conspicuous oblique row of gill openings.

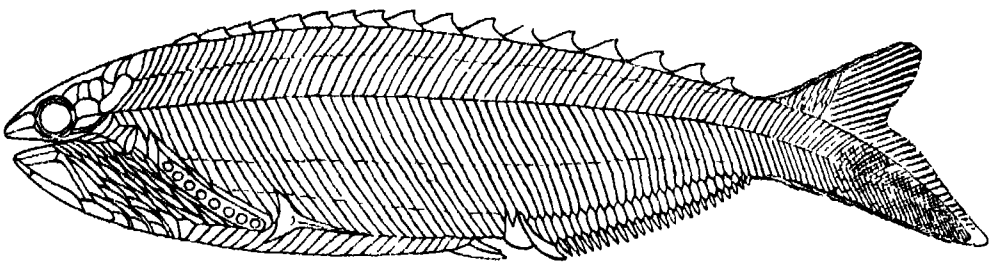

FIG. 2.—Reconstruction of *Rhyncholepis parvulus*, Kiær. × 2. From "The Downtonian Fauna of Norway."

No traces of paired fins have hitherto been observed in these lowly forerunners of the fishes, but Prof. Kiær finds in several specimens a small plate bounding the gill region behind, and a tapering spine which he considers to represent a pectoral fin (Fig. 2). Behind this spine there are apparently sometimes a few fin rays. Pelvic fins are entirely unrepresented. Enlarged scales only mark the cloacal opening and arm the front of the anal fin.

There are many more interesting details, for which it must suffice to refer to the memoir itself. Prof. Kiær not only describes them, but also concludes with an exhaustive discussion of the affinities of the Anaspida as they are now understood. Their anatomy, of course, can only be inferred from the hard dermal armature which is the sole part represented in the fossils. The single median nostril and the relative proportions of the parts of the brain suggest that the late Prof. E. D. Cope and others were right in regarding the earliest fishes as belonging to the same class as the existing lampreys and hag fishes. Even Prof. Kiær's discovery of evidence of ordinary jaws and rudiments of paired pectoral fins does not appear to him to invalidate this conclusion. The lampreys, which are obviously degenerate members of their race, may well have lost the structures in question since the early geological period to which the Norwegian fossils date back. The Downtonian genera indeed represent the heyday of the class, when the higher fishes were only just beginning to appear.

Prof. Kiær is led finally into even wider speculations as to the origin of the paired fins in fishes. He thinks the new discoveries indicate that a pair of pectoral fins appeared first, and then extended backwards as a paired fringe, of which eventually the pelvic fins were the sole persistent remnants. There may be differences of opinion on these and some other inferences, but Prof. Kiær's memoir is one of the most inspiring contributions to palæichthyology that has appeared in recent years, and we eagerly look forward to the promised continuation of it.

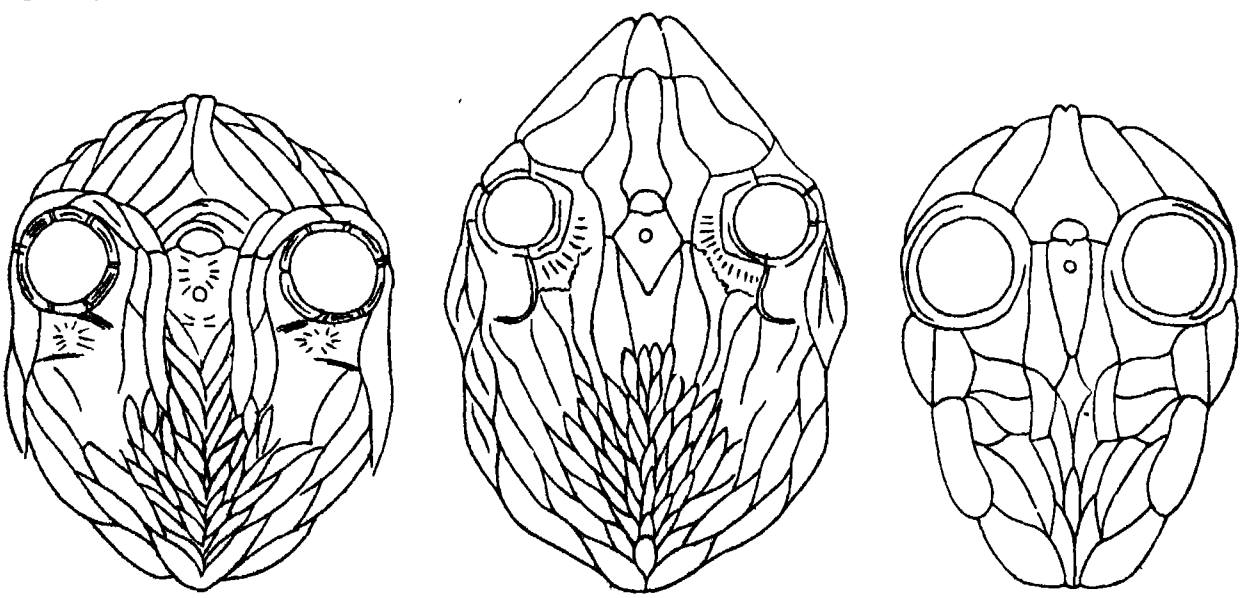

FIG. 3.—Cranial roof in schematic sketches of the Norwegian Anaspida. *a*, Pterolepis; *b*, Pharyngolepis; *c*, Rhyncholepis. From "The Downtonian Fauna of Norway."

Biographical Byways.[1]

By Sir ARTHUR SCHUSTER, F.R.S.

4. KIRCHHOFF (1824–1887) AND BUNSEN (1811–1899).

IN the controversies that excited at one time a good deal of feeling with regard to the part played by different men of science in establishing the principles of spectrum analysis, some confusion was caused by the ambiguous meaning of the word "analysis." The term may apply to the separation of the spectrum into its constituent homogeneous radiations, or it may denote a method to identify the constituents of a chemical compound by the light it emits when raised to incandescence. To avoid the ambiguity, I introduced in 1882 the word "Spectroscopy," to indicate the physical side of this branch of science. With regard to the use of the prism as an instrument of chemical analysis, there can be little doubt that Kirchhoff and Bunsen first demonstrated its practical importance, though Wheatstone had clearly indicated its possibility.

I worked for one year with Kirchhoff at Heidelberg (1871–72). Those were not days of extensive and well-equipped laboratories. Next to Kirchhoff's private study, in the building which served as his residence, one room only was available for advanced work. Its chief occupant was Lippmann, who was working at his capillary electrometer. My table was by the side of his, and having placed myself entirely at Kirchhoff's disposal, he asked me to test an instrument he had devised for the study of metallic reflexion. Nothing came of it, partly because the instrument did not prove suitable for the accurate study of elliptic polarisation, and partly because my measurements were not very good owing to the astigmatism of my eyes, which had not at that time been recognised. The only other advanced student was Kamerlingh Onnes, who was experimenting with a pendulum designed to demonstrate the turn of the plane of vibration due to the rotation of the earth. He had to work in the lecture room next door. There was only one other room, and that was used for elementary exercises. One exercise was set aside for each week, and every student—about eight altogether—had a morning or afternoon assigned to him for carrying out the experiment. There was one weekly lecture in which the results were criticised and the succeeding exercise explained.

During my stay at Heidelberg, I was anxious to repeat an experiment I had previously performed on the spectrum of nitrogen. There was no glass-blower in Heidelberg and no means of obtaining a Geissler tube. Kirchhoff, to whom I appealed, advised me to consult Bunsen, who offered to let me use his laboratory, where I could find the necessary appliances. I had to confess that I was not sufficiently expert in glass-blowing to make the tube myself. He seemed rather amused, took me to a little room and spent the next half-hour at the blow-pipe. When the tube was ready, further difficulties arose. Bunsen gave me a very inefficient induction coil and insisted on my using a bichromate battery; but he would not allow the zinc plates to remain in the solution for more than two or three seconds, watching me all the time. I could not get a proper start and had to give up the experiment.

There are always innumerable stories about Bunsen illustrating his absent-mindedness and simplicity of character. Many of them will be found in Roscoe's "Reminiscences."

I attended Bunsen's elementary lecture course, which began at seven o'clock in the morning during the winter and at six in summer; but one had to be in the lecture theatre well in advance of the hour fixed, because the time was taken from a very erratic clock in this room. Whenever Bunsen was ready to start, he sent his assistant in to set the clock at six or seven as the case might be, beginning the lecture sometimes a quarter of an hour too early or too late by the real time.

There could be no greater contrast both in appearance and manner than that presented by the two men. Kirchhoff, sharp-featured and always correct and precise: Bunsen, with the appearance of a prosperous farmer, and a somewhat cynical but at the same time good-natured smile. New discoveries almost worried Kirchhoff. they amused Bunsen. The effect of light on selenium happened to be first published when I was at home on a holiday, and on returning to Heidelberg I mentioned it to Kirchhoff. His reply was: "I should not have believed that such a curious fact could have remained undiscovered until now." Kirchhoff's lectures were prepared with extreme care and delivered with precision. He is reported never to have missed one during the tenure of his professorship at Heidelberg, but the record was certainly broken on one occasion. "I regret to announce," he said on a certain Thursday at the conclusion of one of his lectures, "that circumstances prevent my meeting you to-morrow." The "circumstances" were that he was going to get married, and the honeymoon lasted from Friday till Monday, when he was at his desk again.

When both men had retired and were nearing the end of their lives—one at Berlin and the other at Heidelberg—I occasionally went to visit them. Kirchhoff's interests were confined to the days that were gone. He admired Maxwell for his work on the kinetic theories of gases. "He is a genius," he said, "but one has to check his calculations before one can accept them." He admired Lord Kelvin for his vortex theory of matter. "I like it," he remarked, "because it excludes everything else," and he added with a sigh: "If only it could explain gravitation." Bunsen liked to talk about new ideas. "Tell me all about the experiments of Hertz," was his first remark on one occasion; and in spite of his almost complete deafness, he had a way of understanding when the subject interested him.

It may be worth while to record the scepticism of Bunsen with regard to the chemical identity of diamond and carbon. He considered the evidence to be insufficient, depending in great part on a single reaction of the gas produced in the combustion of the two bodies. A more convincing test was the demonstration that equal weights of the two bodies produced equal weights of the products of combustion; but all depended here on the accuracy of the measurement, which probably was not very great. My information came from Sir Henry Roscoe, who repeatedly alluded to it in conversation. Engaged at the Cavendish

[1] Continued from p. 89.

laboratory on the spectrum of oxygen, I took the opportunity of placing a diamond inside a platinum spiral in an oxygen vacuum, and raising the spiral to a red heat by means of an electric current. The characteristic spectrum of an oxygen compound of carbon at once appeared, leaving no doubt as to the nature of diamond.

The examination for the doctor's degree at Heidelberg in those days was a purely oral one. The candidate was, in addition, supposed to send in a dissertation, but if this was not ready at the time of the *viva voce*, his degree was conferred on the latter alone, subject to the condition that he deposited a sum of money, which, so far as I recollect, amounted to 10*l*. This was returned if the dissertation was sent in and approved within one year. Three subjects had to be chosen, for example, physics, mathematics, and chemistry, of which one formed the principal and took up an hour. For the two others, half an hour was considered to be sufficient. The candidate, when ready, gave notice to the proper authority, and was in due course summoned to present himself on a certain day at seven or eight o'clock in the evening No account was taken of attendances or period of study Kirchhoff had the reputation of being a very strict examiner. When at the beginning of the year which I intended to spend at Heidelberg, I asked him how far I was expected to know the more mathematical branches of the subject, the only answer I got was: "I shall examine you in physics." All professors of the faculty received a fee for being present at the examinations, and the faculty of philosophy included all branches of arts as well as of science: this naturally secured a good attendance.

During my visit to Konigsberger, the examiner in mathematics, he told me that Kirchhoff was very fond of asking questions about the potential. This reassured me, as I felt pretty safe in that subject, but it turned out that the examination was all on optics. The candidate sat at a long table, surrounded by about twelve severe-looking individuals, most of whom were perfectly ignorant of scientific subjects. As I had not passed the "Abiturienten Examen," which is the school-leaving test, I had to submit to an additional examination in Latin; but the examiner told me, during my visit to him, that he would pass me however badly I did, and indicated the particular book in Cæsar's "De Bello Gallico" out of which he would ask me to translate a passage. I have a vivid memory of the mournful shaking of heads that went round the table when I translated "frumentum" with "Korn," which in German means "rye," instead of with the proper word which is "Getreide." An hour's *viva voce* can, of course, cover a good deal of ground, for, as soon as the examiner is satisfied that the candidate can answer a question satisfactorily, he at once passes on to another. After the first hour, a quarter of an hour was spent on light refreshments consisting of wine and cakes, and then the examination in the two secondary subjects began. Finally, the candidate was asked to withdraw, and after a few minutes' interval the result was announced to him. If successful, he was summoned to present himself to the Pro-rector next day. The degree was actually conferred after he had delivered an oath in Latin promising many things, one being that he would not take a degree at another German university.

All through the examination it appeared to me that the examiners rather took the part of advocates of the candidates against the gallery of dummy professors who were paid to be present. When I got into a muddle with Kirchhoff over a question involving the wave surface and he had not spotted my mistake, he only said, "We both have been rather stupid over this," and then started another subject. When I could not answer one of Konigsberger's questions he said. "There is no need for you to know this; I only asked you on the chance." As a matter of fact, I did know it, but failed to recognise the German expression which he used.

While I was considering the subject of my promised dissertation, I happened to meet the chief librarian of the university, who expressed the hope that I would default, for the reason that the forfeited deposits became the property of the University Library, which depended on this form of revenue.

Obituary.

DR G. D. LIVEING, F.R.S

BY the death of Dr. George Downing Liveing shortly after his ninety-seventh birthday, the University of Cambridge has lost the last of that small band of men who some sixty years ago set on foot the movement which proved the foundation of the present science school in that University. He was the eldest son of Edward Liveing, of Nayland, Suffolk; entering at St. John's College, Cambridge, in 1847, he was classed as eleventh wrangler in 1850, and as the first among the six who took the Natural Sciences Tripos in 1851, the year of its creation. After a short period of work under Rammelsberg in Berlin, he became a fellow and lecturer at St. John's College in 1853. In 1860 he married Catherine, daughter of the Rev. R. Ingram, of Little Ellingham, Norfolk, and thus automatically vacated his College fellowship in accordance with the old University statutes; in the same year he became professor of chemistry in the Military College at Sandhurst, but continued to teach in the St. John's Laboratory.

The Rev James Cumming, F.R.S., occupied the chair of chemistry from 1815 to 1861, and Liveing, who had acted as deputy during the last two years of Prof. Cumming's life, was elected into the chair in the latter year. Liveing retired from the professorship in 1908; the University then conferred upon him the honorary degree of Sc.D. and appointed him an emeritus professor. He had been a professorial fellow of his College since 1880 and was elected into a fellowship again in 1908; in 1911 he became president of St John's College. For many years he held the responsible and confidential office of Chancellor's secretary, an honorary official whose duty consisted in keeping the Chancellor of the University informed on all material happenings. In addition he served for long as a Borough and County Justice of the Peace, and was punctilious in the performance of his magisterial duties.

On his return from Germany in 1852, Liveing conceived the idea of providing instruction in practical chemistry for the medical students; no chemical laboratory existed in the University and one was equipped in a cottage on the west side of Corn Exchange Street, the fittings being improvised and oil and spirit lamps being used in default of gas. St. John's shortly afterwards built a small laboratory for Liveing, and this he used until long after he became professor in 1861. By this latter date, and largely as a result of the insistence of such progressive spirits as Liveing, the University had decided to build science laboratories; but the University was poverty-stricken, and for this and other reasons the oldest part of the present chemical laboratory was not built on the site of the old Botanic Garden until 1888. The difficulties which Liveing had to surmount in inaugurating a chemical school in Cambridge would have disheartened a man of less determination. His stipend was 100*l* per annum, paid by the Government and subject to the deduction of Treasury fees amounting to four guineas. As he has himself said, men in those early days had to devote their means as well as their wits to the service of the University. Until his retirement in 1908, Liveing financed the chemical laboratory as a private venture, and he informed me that he declined to submit his accounts, when challenged in later years by the suggestion that he had been drawing a large revenue, because he was ashamed to disclose to his colleagues how large a sum he had thus contributed from his own resources.

Prof. Liveing lectured on heat as well as on chemistry, but in 1871 James Clerk Maxwell was appointed to the Cavendish professorship of experimental physics, a new chair established largely by the exercise of Liveing's influence. Maxwell commenced to deliver the lectures on heat in the chemical lecture-room in October 1871. Later, Liveing espoused the cause of other new subjects in Cambridge; thus, he housed the beginnings of the present flourishing school of agriculture in his own laboratory, and protected and encouraged it until it became independent under the auspices of the Drapers' Company. In a similar way he devoted his energies and money to the establishment of the Cavendish College, an institution for the accommodation of impecunious students. This enterprise soon stopped for lack of funds, and the building is now the Homerton Training College for teachers.

Prof. Liveing was elected into the Royal Society in 1878, and in 1901 received the Davy medal for his spectroscopic researches—"one of the most valuable contributions to this department of chemical physics yet made by British workers." He joined the Chemical Society in 1853, two years before Roscoe, and shortly after his first paper appeared—"On the transmutation of the elements"—in the "Cambridge Essays," first series, for 1855, this little note is characteristic in its breadth of knowledge, its elegance in phrasing, and its economy of words. A few short papers on geological and minor chemical subjects followed, and in 1878 began the great series of memoirs on spectroscopy in conjunction with the late Sir James Dewar, who had been appointed Jacksonian professor of natural philosophy in 1875. The close and intimate friendship which existed between Dewar and Liveing was very striking; both were men of strong personality, but no two men could have presented a greater contrast in outlook, tastes and all essential characteristics. Yet each held the other in profound esteem, and neither ever said a word in criticism of his colleague; without this absolute loyalty, the happy collaboration of Liveing and Dewar could not have persisted for nearly fifty years.

Liveing's scientific eminence will repose on these joint spectroscopic papers; the skill which he displayed in the development of experimental methods and his infinite patience as an observer resulted in the collection of an enormous mass of accurate data concerning the spectra of the elements which is still in course of interpretation. During his latter years Dr. Liveing occupied himself with the publication in book form of these researches, the "Collected Papers on Spectroscopy," by Dewar and Liveing, was issued by the University Press in 1915. He read his last paper, entitled "The Recuperation of Energy in the Universe," before the Cambridge Philosophical Society on May 7, 1923, and was engaged on experimental work connected with certain ideas put forward in that paper until but a few weeks before his death.

It is difficult to appraise the achievements of one, just passed away, who had left his student days behind him before Frankland had stated the doctrine of valency and before Kekulé had devised the structural formulæ of the chemist. Liveing had been the personal friend of Dr. Whewell, the great Master of Trinity, W. H. Miller, the founder of our present system of crystallographic nomenclature, Adam Sedgwick, Sir Joseph Hooker, Michael Foster, Sir Gabriel Stokes, Sir George Airy, de Morgan and Charles Darwin, he had studied under Rammelsberg, Mitscherlich, Rose and Magnus. He once mentioned to me that he and Hooker, after some preliminary discussion, walked over to see Darwin for the purpose of hastening the publication of the "Origin of Species," which appeared in 1859. In his conversation, always sprightly and vivacious, he seemed often trying to translate our later knowledge into terms of the science of seventy years ago; as befitted one who belonged to the age when the collection of facts was the main objective of science, he was apprehensive as concerned the vast theoretical flights of modern physics and chemistry. Indeed, in his presidential address to Section B of the British Association in 1882, he expressed his distrust of the graphic formulæ of the organic chemist in terms which must be considered as vigorous, coming from one temperamentally so cautious in judgment and so moderate in expression. In talking with Liveing and hearing his statement of long obsolete chemical views,

> "Told, when the man was no more than a voice
> In the white winter of his age, to those
> With whom he dwelt, new faces, other minds,"

one began to realise the difference between the science of seventy years ago and that of to-day, and to speculate as to what our survivors seventy years hence will think of the science of the future. At the same time, and although an authority on the older chemical knowledge, Liveing always maintained an excellent appreciation of recent progress.

Like many other men of robust habit and great vitality, Liveing found it difficult to understand why

his contemporaries dropped out and passed away; declining health seemed to him as due to lack of resolution. He was an enthusiastic gardener, and when well past his ninetieth birthday engaged in all the manual toil incidental to the care of a large garden; after this work had become too heavy he took his exercise by walking, and, in fact, his last illness resulted from a collision with a cyclist. His memory of long-past events was remarkably clear until quite recently, but he sometimes forgot that others could not reach so far back into the past; a few months ago, whilst still in full mental vigour, he expressed surprise that I had not noticed the splendour of Donati's comet—in 1858.

Liveing shirked publicity and rarely spoke in the Senate House because, as he said, he feared being betrayed by provocation into expressing his views—formed with care and then held tenaciously—in terms which might flavour of exaggeration. But whilst others wrangled, Liveing worked, and he will be remembered as the last of that small band of Victorians who possessed themselves of a secluded and conservative institution with splendid traditions and passed it to their successors as a great modern University. A further reason for the rarity of his public utterances lay in the meticulous conscientiousness with which he carried out any duty undertaken; he attended every meeting of the numerous committees and councils of which he was a member, and the sheer labour which he devoted to the study of the questions concerned left him with little leisure or desire to influence others by the spoken word. But the counsels of one so wise, so prudent and so experienced were often sought and were always given in careful and measured terms. With the death of Prof. Liveing, the University has lost one of its most devoted servants, science has lost a pioneer whose early work will long serve as a starting-point for fresh advances, and a great gentleman has passed away.

W. J. POPE.

MR. W. WHITAKER, F.R.S.

THE death of William Whitaker on January 15, though for some weeks it had been clearly imminent, will be felt none the less as a deep personal bereavement by his many friends. The picturesque figure so familiar at the meetings of the British Association, the alertness in body and mind, even after fourscore years and more had laid their burden upon him, but, above all, the geniality which endeared him to all he met, will long be remembered. As a geologist he was a pioneer in the elucidation of the Tertiary strata and the superficial deposits of the south and south-east of England, second only to Prestwick in that branch of the science.

Born in London on May 4, 1836, Whitaker was educated at St. Albans Grammar School and University College, London. At the age of twenty-one he was appointed to the Geological Survey, and continued in that service until 1896. His work lay almost wholly in the London Basin and in the neighbouring counties. The original one-inch geological maps were largely the work of his hands, but he was indefatigable also in collecting records of artificial sections, wells, boreholes, and the other openings which abound in and around London. His labours culminated in the production of the Geological Survey Memoirs on "The London Basin," "The Geology of London and Part of the Thames Valley," and other smaller works. These volumes form standard works of reference and provide the basis on which much of the later literature is founded.

Among other records collected by Whitaker were those relating to the first deep borings that reached Palæozoic rocks under the Tertiary and Secondary strata of the south of England. By their aid he was enabled to trace variations in the development of these strata and to sketch broadly the form of the Palæozoic floor and the distribution of the rocks forming it. The possible existence and situation of concealed coal-fields had come up for consideration, and so long ago as 1889 he wrote "that Coal Measures are likely to occur somewhere along the line of the Thames Valley, or in neighbouring tracts. . . It is rash to attempt to foretell the future, but it seems to me that the day will come when coal will be worked in the south-east of England" ("Geology of London and Part of the Thames Valley," p. 46).

Whitaker retired from his official post at the age of sixty, in order to pursue economic geology. As a consulting geologist on sanitation generally, and on questions of water-supply especially, he attained a high reputation. But he still took pleasure in rendering service to the Geological Survey. A long series of memoirs on county water supplies from underground sources testifies to the diligence with which he collected records of wells and springs, and to the skill with which he interpreted them. This work he continued almost up to the last.

The history of the literature of geology occupied much of Whitaker's spare time. For some years he made "The Geological Record" his especial care, and he also compiled many lists of geological books and papers relating to counties, a task that might have proved tedious to one of less pronounced bibliographical tastes. Though much of his work was of this more or less statistical character, there stands to his credit a great record of original research. In addition to the many official memoirs of which he was author or part-author, his papers on Subaerial Denudation, on the Chesil Beach, and on Water Supply from the Chalk may be selected for mention. He was not given, however, to theorising and was never drawn into controversy.

The high esteem in which Whitaker was held by his fellow-workers is shown by the offices he was called upon to fill and the honours he received. Elected to the Geological Society in 1859, he served on the Council in 1873 and many years after, as president in 1898–1900, and as vice-president, 1901–2. In 1886 he was awarded the Murchison Medal, and in 1906 was the second recipient of the lately founded Prestwick Medal, a particularly appropriate recognition of his work in the field in which the founder of the medal had laboured. In 1923 he received the Wollaston Medal, the blue ribbon of British geology. He was elected to the Royal Society in 1887, and served on the Council in 1907–9. He presided over Section C of the British Association at Ipswich in 1895 and gave an illuminating address on the underground geology of that part of England. He was president also of the

Geologists' Association and of other societies. At the time of his death he was an honorary member of the Geologists' Association, of the Geological Societies of Liverpool, Manchester, and Yorkshire, of the Philosophical Society of York, of the Belgian Society of Geology, and correspondent of the Academy of Natural Science of Philadelphia

Whitaker made many a friend, but never an enemy. Indeed, it is impossible to suppose that with so kindly a nature he could speak an unkind word. To the younger generations of geologists he never failed to lay open his stores of knowledge, or to impart the enthusiasm with which he had himself been inspired. The attainment of the truth was the dominant motive with him, and it gave him as much pleasure that it should be attained by others as by himself Unselfishness, transparent honesty, and kindliness were the conspicuous features of his truly lovable character.

A. STRAHAN.

THE death on October 29 of Dr. Ernst Konig, of the famous dyeworks at Hochst-am-Main (formerly Meister, Lucius, and Bruning) at the early age of fifty-five, is recorded by the *Chemiker-Zeitung*. Konig's reputation rests securely upon his well-known researches in the field of photochemistry. Born at Flensburg in Schleswig, he graduated at the University of Leipzig, where for a very brief period he acted as assistant to Prof. Stohmann. In 1893 he entered the service of the dyeworks at Höchst, where he eventually attained a position of the highest responsibility At first he undertook the investigation of new coal-tar colours, but his chief interest lay in their application to photographic processes. In 1902 a photographic department of the works was formed under his direction, and two years later a new kind of three-colour collodion process, the *pinachrome* process, was invented. This was followed by the application of dyes to chromate-gelatin emulsions and the development of the *pinatype* process. He also devoted much attention to the production of various light-filters and desensitisers. One of the most important of his discoveries was that of the panchromatic plate. The problem of extending the region of sensitiveness of the emulsion beyond the yellow into the red and even far down into the infra-red region was solved by employing as sensitisers derivatives of quinoline, containing auxochromic groups in the benzene nucleus. König was also the author of numerous scientific papers and books on photographic subjects.

WE regret to announce the following deaths:

Mr. G Abbott, well known for his geological studies, and one of the founders of the South Eastern Union of Scientific Societies, on January 12, aged eighty.

Right Rev. L. C Casartelli, Roman Catholic Bishop of Salford, and formerly president of the Manchester Egyptian Association, of the Manchester Egyptian and Oriental Society, and of the Manchester Statistical Society, and the author of numerous papers in oriental journals and in the proceedings of the Manchester Statistical and Geographical Societies, on January 18, aged seventy-two

Dr. Clement Dukes, for thirty-seven years physician to Rugby School, and author of "Essentials of School Diet" and "School Health," on January 18, aged seventy-nine.

Dr J McT E. McTaggart, fellow of Trinity College, Cambridge, since 1891, and the author of "The Nature of Existence," on January 18, aged fifty-eight.

Dr Julius Morgenroth, a professor at the Robert Koch Institute for the study of infectious diseases in Berlin, and a former student and colleague of Paul Ehrlich, known for his work on immunity, on December 20, 1924, at the age of fifty-three.

Current Topics and Events.

GREAT encouragement for industrial research is contained in a notification just made to the chairman of the British Cotton Industry Research Association to the effect that 65,000*l* is to be received by the Association as an addition to its present income—most welcome aid towards the maintenance of the laboratories at the Shirley Institute, Didsbury The trustees of the Cotton Trade War Memorial Fund, acting on a recommendation from the Cotton Reconstruction Board, have decided, subject to the approval of the Board of Trade, to make this grant in instalments, 5000*l* for the year ending June 30, 1926, and 20,000*l* for each of the three years ending June 30, 1927, 1928, and 1929 Some four years ago the Cotton Reconstruction Board made a grant to the British Cotton Industry Research Association of 200,000*l*, a sum from which a large part of its income has ever since been derived, and the fact that the trustees have now decided to continue their help shows their great confidence in the ultimate benefits that will accrue to the cotton trade as the result of scientific research. Nothing could more strongly signalise the value of science to the industry than a gift such as this; and their appreciation of what they describe as "the good work being carried out by the Shirley Institute" is bound to encourage not only the staff there but industrial research workers throughout Great Britain. Further, they feel that this work should be made even more widely known to the trade and to the workpeople themselves, showing that the real importance of applied science is now being more fully realised. Thus the labours of chemists, physicists, botanists, and engineers on the fundamental problems presented by cotton are being justified.

THE Dominion of Canada, which extends in an irregular way on a 3000-mile base line, with a scattered population and cities widely separated, will benefit largely by radio communication In accordance with the agreement made between the Marconi Co. and the British Post Office, the Canadian Marconi Co. has begun to construct a "beam" station in Canada for communication with the stations which the Marconi Co is to erect in England. The transmitting station is being erected at Drummondville, 50 miles east of Montreal, where the main office is situated, and the receiving station is at Yamachiche, which is about the same distance from headquarters. Both sections

will be operated from Montreal by a "remote control" method. The work was begun last November, and although the temperature has often been 20° below zero and the workmen have to wear gauntlets to prevent frost-bite by accidentally touching metal, good progress has been made The transmitting aerials for communication to England are supported on five masts of steel lattice work and each is 300 ft. in height For communicating with Australia, five 250-ft masts are employed The power required for each station per beam is 150 horse-power and is obtained from a local power supply company. The power delivered to the anode of the valve required for each beam, however, is only about 25 horse-power. Both the sending and receiving stations which are to be erected in England will be operated by remote control from the Central Telegraph Office in London When the stations are completed, Canada will be brought into much closer contact with England and with Australia It has been agreed to fix the rates so as to attract the largest volume of traffic. It is hoped that in this way the trade between the Dominions will be fostered to the advantage of the British Empire as a whole.

SIR WILLIAM BRAGG, in his Friday evening discourse at the Royal Institution on January 16, dealt with the investigation of the properties of thin films by means of X-rays. The reactions of bodies must generally depend upon the nature and condition of the surfaces at which they meet, therefore the thin surface film is of great importance. It may differ in structure, composition, or other condition from the internal portions of the body, and the fine vision of the X-rays may well help in its investigation. The X-rays cannot take notice of a single film or layer, their especial power lies in the measurement of the spacing of a set of layers But the general laws of arrangement which are discovered in the crystal must be applicable to the thin film, and in some cases the thin film may be looked upon as one single layer of a crystal. Thus it has been possible to examine some elements of the structure of the fatty acids, alcohols, paraffins, and similar long-chain substances: to measure the thickness of the layers in which they lie, and to confirm with numerical amendments the previous measures of Langmuir, Hardy, Adam, Perrin, and other workers It is found also that the fatty structure of these substances is shared by many more solid crystals, in which also the molecules lie more or less across the flake: bound together by side-to-side ties which are stronger than those at the ends It is a general characteristic of crystalline structure, more particularly in the case of organic substances, that each molecule occurs in one or other of a small number of definite orientations: and that a molecule of one orientation binds together molecules of other orientations. The characteristics and probably the strength of the crystal depend upon the fact. It may explain the strength of the "black spot" of the soap film: the two layers of oleic acid on the two sides of the film are individually non-crystalline; but when they meet—the intermediate liquid being expelled—the full symmetry of the crystal can be realised, when all the orientations are present. The flaky substances are often greasy because of the toughness of each layer and the ease with which they slide on one another, pressure and rubbing tend to encourage the formation of the flakes in such substances as stearic acid

SIR OLIVER LODGE delivered the second of his series of talks on the ether under the auspices of the British Broadcasting Company at 2LO on January 20, taking as his title "Vibrations and Waves and what they signify" Sir Oliver stated that the ether is so uniform that it as difficult for us to discover it as a deep-sea fish would find it difficult to discover water All knowledge has to make its way slowly and painfully against a mass of prejudice and inertia nevertheless it is better to be slow in accepting the truth than to be ready to accept falsehood: a certain amount of opposition may be salutary Meanwhile our theories do not alter facts: the facts are there all the time, and are independent of what humanity thinks of them Some things we have learnt which were unknown to the ancients, but in time we too shall be ancients, and our descendants will wonder at the blindness and stupidity, even of our learned men We used to try to explain ether properties in terms of matter we now perceive that we must explain matter in terms of ether We now realise that the clue to the physical universe lies in electricity and magnetism We had thought that the way towards the light must lie in the open country of ordinary mechanics, we are now plunging into the wood—the forest of ether-dynamics But glimpses of illumination have been caught through the branches, and have heartened the younger generation of physicists with a great enthusiasm Those who have insight and intuition know that through this strangely unpromising country lies the road to reality.

ATTENTION is directed, in a leading article in a recent number of the *Scottish Naturalist* (December 1924), to a modern development in the protection of wild life in the United States of America. The sportsman has entered into competition with the naturalist in the race for the creation of animal sanctuaries. The reason is obvious The development of American legislation for the protection of wild animals shows very distinctly that a progressive disappearance of sporting mammals and birds has been proceeding for many years. The result is that, in the words of the Hon. John W Davis "Hunting is fast losing its character as one of the most democratic of sports. The really good shooting-grounds are rapidly being taken up by clubs too expensive to be patronised by the average sportsman Drainage of great marsh and swamp areas, the natural breeding- and feeding-grounds of wild fowl, has threatened these with extinction We must establish shooting-grounds so that the man of average means may enjoy the ancient, healthful, and democratic pastime of shooting, and *we must have the refuges if we are to continue to have the wild fowl.*" Accordingly a "Game Refuge Bill" has been introduced into Congress with the whole-

hearted support of the American Game Protective Association and of sportsmen generally. The combination of sportsmen and naturalists in an endeavour to protect wild life is a movement of great significance, for, as the *Scottish Naturalist* points out, "the sanctuary is the best solution of the problem of the preservation of the native fauna."

A REPORT on excavations at Ur by the Joint Expedition of the British Museum and the Museum of the University of Pennsylvania since November 1, when the season's work began, appeared in the *Times* of January 14. The main object of the work this year will be to discover whether the great ziggurat or tower was an isolated structure or formed part of a more considerable complex. Excavations to the north-west of the tower, between it and the enclosure wall, have brought to light living quarters and storerooms of the priests of the Persian period which overlie a courtyard laid out by Nabonidus. Beneath the latter was a range of buildings dating from the 16th century B.C., and beneath this again were the walls of shrines erected by the kings of Isin and Larsa (*c.* 1600 B.C.). Underneath this stratum was found the terrace wall of Ur-Ungur, the builder of the ziggurat. Inscribed nail-shaped cones of fired clay were found driven into the wall, this being the first indication ever found of the use of these objects. On the south-east side of the ziggurat a "Hall of Justice" has been brought to light, a structure originally a triple gateway, of which the back door had been blocked up by a later cross wall. Mud-brick chambers had been built alongside, in or on the ruins of the double wall in which the gate tower had originally stood. An inscription on a gate socket records the restoration of the fallen tower about 650 B.C. The original gate has yet to be discovered. It is known that it had been repaired by Ishme-dagan of Larsa by 2000 B.C.

AFTER an exhaustive inquiry by a commission which visited Europe, Japan resolved in 1921 to make the metric system of weights and measures compulsory throughout the Empire and took steps to secure a primary standard metre for the country. On the advice of Prof. Nagaoka, it was decided to obtain interference apparatus similar to that used by Benoit, Fabry, and Perot, who found that the red line emitted by cadmium vapour had the wave-length $0.64384696 \times 10^{-6}$ metre. According to a memorandum by Mr. F. Twyman on the measurement of standards of length in wave-lengths of light, the apparatus has been constructed by Messrs. Hilger, and in the course of his study of the literature on the subject of the metre, Mr. Twyman has noted how isolated the British are becoming in adhering to the yard as the standard of length, and how little is known about this standard to the degree of precision at present attainable. The British Empire, the United States, China, Paraguay, and Turkey appear to be the only countries in which the metric system is not now compulsory, and there appears every likelihood of China adopting the system in the near future.

KNUD RASMUSSEN, the Danish explorer, has been awarded the Charles P. Daly Gold Medal of the American Geographical Society for 1924 for his explorations in Greenland and northern North America. For twenty-five years he has studied the life of the Eskimo and explored northern lands. An account of his work and that of his assistants on the second *Thule* Expedition has appeared in the *Geographical Review* (vol. 8, 1919, pp. 116-125, 180-187). His latest expedition—the so-called fifth *Thule* Expedition—occupied three years, and the field of his work included the whole stretch of territory between Greenland and Siberia, as well as the study of the folklore, language, present distribution, migrations, and particularly the foci of migrations of all the known Eskimo tribes and families. The results will be issued in a series of volumes and maps. Among the most noteworthy of Rasmussen's earlier publications are "Greenland by the Polar Sea," "Eskimo Folk Tales," and "The People of the Polar North."

THE *Indian Antiquary*, which has been conducted by Sir Richard Temple as editor-proprietor for more than thirty years, has been transferred to the Royal Anthropological Institute and is being published by that body under the authority of its Council as from January 1. It will continue under the joint editorship of the present editors, Sir Richard Temple and Mr. S. M. Edwardes, with S. Krishnaswami Aivangar as Indian editor. In policy and scope the *Indian Antiquary* will remain unchanged, and will continue to deal with the history, ethnology, archæology, linguistics and folklore of India. The Council of the Royal Anthropological Institute has authorised the formation of an Indian Section of the Institute the function of which will be to afford a meeting-place for discussion among those in Great Britain who are interested in the anthropology, archæology and history of India, to correlate the results of research in these subjects, and also to co-operate with workers in India. The *Indian Antiquary* will serve as the official publication of this Section and in it the proceedings of the Section will appear.

PROF. BOHUSLAV BRAUNER, professor of chemistry in the Charles' (Bohemian) University at Prague, has been awarded the cross of a chevalier of the French Légion d'Honneur for his scientific work in chemistry.

DR. ALEXANDER WETMORE, of the U.S. Biological Survey, has been appointed superintendent of the National Zoological Park, Smithsonian Institution, Washington, in succession to Mr. N. Hollister, who died on November 3.

THE Tokyo correspondent of the *Times* announces that Mr. Rockefeller has made an unconditional gift of four million yen (400,000*l.* at par) to the Imperial University Library. It will be remembered that in the fire which followed the earthquake of September 1, 1923, the Library of some 700,000 volumes was destroyed.

WE have received the annual report and statement of accounts for 1923–24 of Livingstone College,

Leyton. The College was founded thirty-two years ago for the purpose of training missionaries in the elements of medicine, and 810 students have taken its courses of instruction during that period The deficit has been reduced by about 42*l.* during the year, but it still amounts to 1067*l.*, and further donations and subscriptions will be very welcome.

On Tuesday next, January 27, at a quarter past five, Dr H R. Hall will deliver the first of two lectures at the Royal Institution on the relations of the prehistoric Greek and ancient Egyptian civilisations, and on Thursday, at the same hour, Sir William Bragg will begin a course of four lectures on the properties and structures of quartz The Friday evening discourse on January 30 will be delivered by Prof J W Gregory on the mountain structure and geographical relations of South-eastern Asia, and on February 6 by Prof R W Chambers on the earliest recorded kings of the English.

The first presentation of the Rivers Memorial Medal for anthropological work in the field, founded by the Council of the Royal Anthropological Institute in memory of the late Dr W R Rivers, will be made at the anniversary meeting of the Institute to be held at the London School of Economics on January 27, at 8 30 As already announced, the first award of the medal has been made to Dr A C. Haddon, in recognition of his work in New Guinea, Torres Straits, and Borneo After the presentation, Prof. C G. Seligman, president of the Institute, will deliver his presidential address on "Some Little-known Tribes of the Southern Sudan"

In connexion with the recent celebration of the bicentenary of Sir Christopher Wren, the Royal Institute of British Architects published a book on Wren and his work (including St Paul's Cathedral), entitled "Sir Christopher Wren Memorial Volume. 1723–1923." The profits of the sale are devoted to the St. Paul's Preservation Fund. The sale of only one thousand copies of the five guineas edition would enable the Institute to hand over a sum of 2000 guineas, which would be acknowledged in the *Times* list in the name of each purchaser as a subscriber of two guineas. Orders, enclosing remittance, should be sent to the Librarian, R I B.A., 9 Conduit Street, London, W.1

A process of direct colour photography is recorded by A. Hoffmann (*Photographic Abstracts*, iv 139), who found that when photographing on a chloro-bromide transparency plate, objects reflected from the surface of a lake were rendered in their natural colours on prolonged development with pyrogallic acid. The angle of reflection proved to be the polarising angle The author found that by using a grainless emulsion of Valenta's formula and exposing with a black glass reflector in front of the lens, on development with 0·1 per cent. pyrogallic acid with relatively large proportions of ammonia and potassium bromide, images in very good natural colours were produced.

An investigator at the mines department testing station at Eskmeals, Cumberland, is shortly to be appointed, and applications for the post are invited. The duties of the person appointed will be to carry out, under the direction of the superintending testing officer, experimental work on problems arising in the testing of safety lamps (flame and electric), the analysis of mine air and mine dust, etc , and to assist the testing officer generally in carrying on the scientific work of the station Applicants must possess good scientific qualifications and have had experience in analytical and experimental work of this character. Forms of application, which must be returned not later than January 31, can be obtained from the Under-Secretary for Mines, Establishment Branch, Mines Department, Dean Stanley Street, S.W 1.

The Scientific Expeditionary Research Association dispatched the *St George* last April on a year's cruise to the Southern Pacific with the object of exploring many of the lesser-known islands and reporting on their natural history, ethnology, botany, marine life, etc An account of the work which has been accomplished was given in our issue of November 8, 1924, p. 681, by Mr J Hornell, the scientific director of the expedition It was intended to complete the cruise by studying the little-known islands south and east of Tahiti; but owing to unforeseeable circumstances, the funds are no longer available Unless about 9000*l.* can be raised at once, it will be necessary to recall the *St George* at what will be the most valuable and promising point of her voyage. An appeal has accordingly been issued, signed by ten members of the Advisory Council, representative of various branches of natural science, archæology, and so on, six of whom are fellows of the Royal Society. Subscriptions should be sent to the secretary of the Association at 50 Pall Mall, S W 1.

The work of the Smoke Abatement League of Great Britain, established in 1909, was dropped during the War and was not taken up again until 1923. Now the League is preparing a great campaign against the smoke nuisance and, with this object in view, is appealing for increased membership and support. We learn also that the valuable papers which were presented at the Manchester Smoke Abatement Conference held in November last under the auspices of the League, together with the discussions, are to be issued shortly in book form Particulars of the League's activities can be obtained from the honorary secretary, Mr. C. Elliott, 33 Blackfriars Street, Manchester.

A very interesting and instructive catalogue (pp. iv + 24) of industrial sands has recently been issued from the Westmoor Laboratory, Chatteris, by Mr. A L. Curtis, who for twenty years has specialised in supplying tested sands, and also clays and refractories, for technical and commercial use It will be a revelation to many that the particular requirements of manufacturers and contractors can be met by so many different kinds of natural and artificially-prepared sands The pamphlet describes more than fifty varieties used for widely different industrial purposes such as glass and pottery manufacture, sand-blast and other abrasive processes, moulding and casting, furnace lining, filtering, cement making

and testing, and less familiar applications in the soap and paint industries. Mr. Curtis has accumulated an enormous mass of data relating to the properties and uses of sands, and he undertakes to advise his clients on the problems that arise. Apart from his commercial enterprise, he is to be congratulated on issuing a pamphlet of unusual educational interest

THE fourth Annual Report of the Animal Breeding Research Department of the University of Edinburgh is a record of research work actively pursued in many directions under the guidance of the director, Dr. F A E Crew The Department is engaged on the problem of wool improvement in Welsh sheep, with special reference to its kemp content, with the object eventually of eliminating this undesirable element from the fleece Hybridisation experiments by crosses with Peruvian merino sheep are also being carried out with the object of improving British wools, and this has necessitated a detailed microbiological investigation of the fibres comprising the fleece of sheep Parallel investigations on the fecundity, fertility, sterility, and general physiology of fertilisation in sheep are in progress and promise results of great importance The list of twenty-one papers issued from the Department in the course of the nine months covered by the report is an eloquent witness to its widespread activities and to the value of the work being carried on there

WE are informed that Messrs. Gurney and Jackson, 33 Paternoster Row, have been appointed official publishers to the Faraday Society, and in future they will deal with all business relating to the sale of Transactions and separate Reports of General Discussions

WE have received from Messrs. Negretti and Zambra a specimen of an ingenious and simple pocket forecaster The instrument consists of three concentric circular discs, the largest of which is two inches in diameter. The instrument is set by first rotating the middle disc so as to bring an arrow on it into coincidence with the appropriate point on a wind direction scale engraved on the outer disc, and then rotating the inner disc so as to set an arrow over the appropriate reading of a barometer scale in inches graduated on the middle disc. The inner disc has three windows, one each for rising, steady, and falling barometer, fitting over a series of code letters A to Z. Through the appropriate window a code letter is read, and this letter selects one of 26 forecasts given on the back of the outer disc The instrument is ingeniously conceived, and can be recommended to those who desire to make the most of their barometer, with the proviso that no simple instrument can be expected to be infallible in dealing with so complex a phenomenon as the weather On the whole, it may be expected to give good results.

Our Astronomical Column.

WOLF'S COMET.—A Copenhagen telegram announces that Prof. Wolf succeeded in photographing this very faint comet again on January 13, at $17^h\ 58{\cdot}5^m$ G.M T (new), its position for 1925·0 being R A. $4^h\ 4^m\ 48{\cdot}0^s$, N. Decl 20° 14′ 54″ The Right Ascension was about $1^m\ 27^s$ less than Kahrstedt's ephemeris, the Decl 12′ greater The orbit elements therefore need considerable modification, but there has not yet been time to do this. The magnitude had declined from 16 to 17, so it is to be feared that the object will not be visible for very long

MINOR PLANETS.—*Astr Nachr*, No. 5341, contains a paper from the Berlin Recheninstitut describing the discovery of minor planets for the period July 1, 1923, to June 30, 1924 The number of discoveries is unusually large, 108, and shows that we are far from exhausting the zone Only 29 of these were sufficiently observed for trustworthy orbits to be calculated and to receive permanent numbers. The numbers assigned are 996 to 1024, so that the 1000 mark is now well passed No 1023 is named Thomana, the others are still unnamed The highest inclination among the new planets is 26° 58′ (No. 1019), the lowest 0° 41′ (No 996) The greatest eccentricity is 0 454 (No 1009), the smallest 0 009 (No. 1020) The periods range from 2 64 years (No 1019) to 6 25 years (No. 1004) A new plan for the provisional numeration of planets is adopted in the new year. The lettering will begin afresh each year. planets discovered in the first half of January will be denoted by AA, AB, AC . . . ; in the second half BA, BB, BC . ., in first half February CA, CB, CC . . , the first letter changing twice a month The system permits the insertion of planets afterwards detected on plates. The year must be prefixed to the letters, but in practice the last two digits of the year will suffice This system will put an end to the present diversity, three independent systems having been in vogue since the War.

STELLAR SPECTROPHOTOMETRY.—*Bull Astron* tome iv. fasc. iii contains an interesting research by M. Jules Baillaud on the distribution of energy in the spectra of stars of types A and B, also of Procyon (type F5). The observations were made at the observatory on the summit of the Pic du Midi (altitude 9384 feet). The curve for Procyon had a maximum at λ425, and resembled that of a black body at a temperature of 7000°. The curves for types A, B do not resemble those of a black body at any temperature. They fall off much more rapidly from their maximum. For type A this occurs in the neighbourhood of λ400, for type B it is at a wave-length even shorter than λ330, which is the limit to which the spectra were studied. The descent from this point is even more rapid than that indicated by Planck's formula for temperature 100,000°. The author concludes that the spectrum of stars of type B arises from the radiation of ionised atoms. He compares the continuous spectrum given by metallic vapours in an arc in vacuo, as observed by M. St. Procopiu.

α Cygni, though of type A, resembles β Orionis closely for the longer wave-lengths but not in the ultra-violet.

Two of the stars included here, γ Cassiopeiæ and α Cygni, were also studied by Plaskett. Baillaud's curve is much higher in the ultra-violet, perhaps owing to diminished atmospheric absorption. He determined the correction for this by observing the same star at different altitudes.

Research Items.

THE MOCK KING AT THE NEW YEAR IN EGYPT.—The December issue of *Ancient Egypt* has as a frontispiece a reproduction of the only illustration extant, fortunately preserved by Rifaud, showing the figure of the mock king degraded as *Abu Nerus*. The only account of this curious survival is given by Dr. Klunzinger in his book, "Upper Egypt. its People and its Products," published in 1878. On the tenth day of September, the first day of the Coptic solar year, each little town chooses from among its own members a king whose rule lasts through a festival of three days. During this period all official rule is abrogated and rigorous criminal investigations are held by the mock ruler, in which heavy penalties are inflicted even on the highest officials, and immense taxes are imposed. Both penalties and taxation are remitted for bakhshish. At the end of the three days the mock king is condemned to death and he (*i.e.* his clothes) is executed by burning The illustration shows that this festival took place at the date harvest Sir Flinders Petrie, in a note on the illustration and Klunzinger's account, refers to a title of the XIIth Dynasty, "New Year King of all the Nobles," which was borne by the highest nobles, and points out that this office, which the form of the title shows to have been annual, would indicate that the New Year King was a survival of an age much earlier than dynastic rule. It was a relic of an earlier kingship of prehistoric times and allowed a semblance of the ancient rule to the nobles of the old race, just as the king of the Saturnalia at Rome preserved among the enslaved aborigines a memory of their former liberty.

NEW CORBICULÆ FROM URUGUAY.—The genus Corbicula has a special interest for the student of post-Tertiary geology inasmuch as though now a southern form, it originally in both hemispheres ranged farther north, inhabiting Britain and Siberia in one, and attaining to Nebraska in the other. The American forms differ from the European in that the former have a slight palial sinus, which is wanting in the latter, and have been placed in a separate subgenus, Neocorbicula, by Fischer. Dall, however, has sought to revive Férussac's name of Cyanocyclas, which was only a synonym for Corbicula Mr. W. B Marshall in this respect has followed Dall when describing an interesting series of Corbiculæ from Uruguay (Proc U.S. Nat Mus, vol. lxvi art 15). Altogether eight new species are described and well illustrated, whilst a most useful list of the seventeen previously described American species, with the original references, is appended.

CINCHONA AND IPECACUANHA IN BURMA.—The Report of the Botanical Survey for India for 1923-24 contains further information as to the progress of the interesting experiment upon the planting of an experimental area (now at Mergui) in Burma with cinchona (see NATURE, April 21, 1923, p. 547, and January 5, 1924, p. 25). The conclusion of a brief description of progress is apparently "to confirm the optimism expressed earlier." With the more equable rainfall of Mergui, it appears that the period of nursery culture may be materially shortened, plants set out as quite small seedlings making such vigorous growth after rainfall that they have formed an area of young Cinchona already ahead of the older plants at the former station at Tavoy, now abandoned in favour of Mergui. So far the species to which this report refers is only *C. Ledgeriana*, but *C. succirubra* is also upon trial. Ipecacuanha is also under cultivation at Mergui, "where it is obviously much more at home than it ever can be in the Bengal plantations." Until now, however, no cropping has been attempted, but the policy of multiplication of stock continued.

BARK SCORCH OF WILLOWS.—A bark scorch of willows, caused by the fungus *Fusicladium salicis-perdum* Tub., has been known as a troublesome disease of willow rods for some time on the Continent. The disease was noted on the rods of willows grown for cutting in a market garden in Lanarkshire, and specimens were sent to the Edinburgh Botanic Garden for diagnosis, where they were examined by Mrs. N. L. Alcock (Transactions of the Royal Scottish Arboricultural Society, vol. xxxviii. part ii. October 1924, p. 128). The disease first appears as patches on the leaves resembling those of "scab" *Fusicladium dendriticum*, Fuckel, on apple leaves. The disease causes later on striking black patches on the bark giving the rod a piebald appearance, and it may also cause a die-back, and the young rod then turns black from the tip downwards. Little is known as to control, but probably a winter wash of copper sulphate would be useful Care should be taken when cutting out the rods to cut down to the stock, and not to leave long stubs Affected rods should be cut out and burnt.

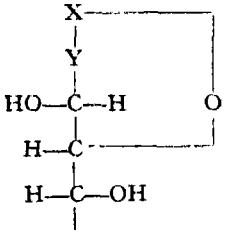
PALÆOZOIC ALGÆ.—Interesting plants from the Old Red Sandstone of Scotland, showing clear indications of algal organisation, are described by the late Dr R. Kidston and Prof. W H Lang in the Transactions of the Royal Society of Edinburgh, vol 53, part iii. (No. 29), pp 603-614 *Cryptoxylon Forfarense* Kidston, described in 1897, is rediscussed in the light of a wider knowledge of Nematophyton, and as a result, it is transferred to the genus as *N Forfarense* Kidston, the pseudo-cellular structure of this species being no longer a bar to its transference to this genus. Two new species of Pachytheca are described, *P media* and *P. fasciculata* The genus includes a number of spherical forms about half a centimetre in diameter, which when split across show a central region or medulla surrounded by a radially striated cortex, composed of more or less evident tubes. In the newly described species, algal filaments can be clearly discerned on microscopic examination of favourable specimens, these run irregularly in the medullary region, and in groups of seven or more fine filaments through the cortical tubes, emerging from the ends of the tubes in a pencil-like group, in what is described as a peripheral "narrow clear zone" The authors suggest that where the algal organisation cannot be clearly made out, specific names should not be attached to specimens of this fossil, which are widely distributed and relatively abundant in certain formations in Britain They conclude that the relatively frequent association of Nematophyton with Pachytheca raises interesting problems as to the condition of life of these contemporaneous organisms, and that the mode of occurrence of both of them and the nature of the beds in which they occur will repay further work and co-operation on the part of palæo-botanists and geologists

SUNSPOTS AND TEMPERATURES.—In a recent pamphlet under the title "Sunspots and Temperature, 1916," Mr. A. H. Wallis, of Kimberley, criticises the conclusion of Nordman and Köppen that there is a tendency in the tropics towards low temperatures at times of numerous sunspots, on the ground that the relationship is not invariably valid and is based on the discussion of smoothed means. He suggests for further investigation a law that sudden rises in the daily sunspot number are frequently associated with

rises of maximum temperature. He apparently has not had access to the variation curves for 25 regions of the earth's surface from 1820 to 1910 prepared by J. Mielke, or to the 97 correlation coefficients worked out by G T. Walker; or he would realise that with a coefficient of only −0 2 or −0 3 in the tropics between the annual temperature and sunspot number, a perfect correspondence cannot be expected Also a negative coefficient in annual means might be perfectly consistent with a positive coefficient over short periods such as a day When, therefore, Mr Wallis claims to find in the course of a single year 199 daily agreements of sign in the departures of spots and maximum temperatures and 155 disagreements, he does not upset existing beliefs, neither does he provide much support for belief in a parallel relationship by an agreement of only 56 2 per cent of cases—his 79·4 per cent appears to be in error. Also during the year in question, his tables appear to contain 27 occasions on which there was an increase of 24 or more between the sunspot number of one day and the next, and in only 16 of these was there a contemporary rise of temperature All attempts to throw light on this interesting subject are welcome, but a further examination must be made before an addition to our knowledge can be claimed.

Investigations of Atmospherics.—All the various irregular noises which are heard in radiophones are classed together as "atmospherics" In long-distance working they are specially objectionable As a large amount of research work, the results of which are not readily obtainable, has been done on the subject, the paper by Dr R L Smith-Rose published in the January number of *World Power* will prove useful to many. The connexion between these noises and neighbouring thunderstorms was discovered at the end of last century by means of a coherer, and use was made of it in France, the owners of vineyards being warned of the approach of thunderstorms During the War the forecasting of thunderstorms was of great value in aviation It has been shown recently that all important atmospherics have their origin in mountainous regions and are due to electrical discharges The range of a disturbance caused by a lightning flash is usually world wide, and there are always sufficient lightning flashes occurring in some part or other of the world to account for all the noises heard in a radiophone. The energy radiated is only a small fraction of the energy required for the local disturbance, and hence radio experts find it difficult to imagine that anything except a lightning flash could produce the observed effects. They also think that the disturbances travelling through the ether must have a high frequency The methods used to eliminate these disturbances are to utilise the phenomena of directional reception, the beneficial effects being apparently more pronounced the shorter the wave-lengths used by the station

Theodolite Observations without Field Illumination.—Difficulties are often experienced, especially by workers in remote regions, in obtaining suitable illumination of the field when observing stars with the theodolite An ingenious attachment, which permits of observations being taken without any field illumination, is described by Mr E. A. Reeves in the *Geographical Journal* for December last A small semi-reflecting glass disc is placed in the focal plane of the telescope objective, taking the place of the ordinary diaphragm Another similar reflector, which is capable of horizontal and vertical adjustment, is screwed over the eye-lens of the eyepiece. When an image of the star is formed on the semi-silvered face of the diaphragm, the transmitted light passes through the eyepiece and emerges as a parallel beam on the eye-lens reflector. Part of this beam is reflected backward on to the diaphragm and again reflected into the eye Two images of the star are thus visible. These coincide only when the star is in the centre of the field. If the star is in any other position, the images part and move in opposite directions, the distance apart being double the error of pointing. The device can be readily fitted to, and conveniently used with, any theodolite if the object-glass is reasonably large. With a 5-in. theodolite, having a 1¼ in. aperture, coincidences can be made with 1st and 2nd magnitude and even smaller stars The device should be of use also in mines and other underground works where lamps have to be used as marks upon which to sight the theodolite



Physical Properties of Single Metallic Crystals.—Dr. P. W. Bridgman describes some physical properties of single crystals of zinc, cadmium, bismuth, antimony, tellurium, tin and tungsten in the Proceedings of the U.S. National Academy of Sciences for October 15, 1924 The properties listed include the elastic constants (which vary greatly with direction), linear compressibilities, linear thermal expansions, and electrical resistance The compressibility of cadmium could not be obtained, owing to the existence of two new polymorphic forms under pressure, the transitions taking place at about 3000 and 6000 kg./cm^2 (20° C.) The electrical resistance also changes slightly at the transition The properties of the new modifications are very similar to those of the ordinary modification Tellurium exhibits negative thermal expansion along the crystal axis The influence of pressure on the electrical resistance of antimony is anomalous; it tends to indicate that resistance is determined by something more specific than the distance apart of the atoms

Harmonic Tidal Constants.—In a paper entitled "Perturbations of Harmonic Tidal Constants" (Proc. Roy. Soc., A, 106, pp 513-526), Dr. A. T. Doodson, secretary of the Liverpool Tidal Institute, discusses some unusual features in the results of harmonic analysis of tidal observations at St. John (New Brunswick) and at Bombay. The principal lunar semidiurnal constituent M_2 at both stations shows three definite perturbations, one of these is of 19-year period, and arises from a failure of the ordinary method of allowing for the 19-yearly variation of M_2 (due to the varying longitude of the moon's node) The ordinary method assumes that two terms of closely similar period in the tide-generating potential will produce terms in M_2 of proportionate magnitude, and affected by the same phase lag. In actual fact this proves not to be the case, particularly at St. John, and the author states that, though the magnitude of the effect makes the explanation very difficult to believe, resonance is at present the only assignable cause St John is of course one of the stations where such a phenomenon is least improbable, since the very large tides in the Bay of Fundy are certainly due to resonance with a "sea seiche." But in addition there is another 19-year term in M_2 which can only be explained as due to frictional forces of considerable magnitude, depending on some higher power than the first (probably the second power) of the speed. This conclusion depends only on the forms of the expressions for the tidal elevations, and, while it is in general agreement with Dr. H. Jeffreys' calculation of frictional losses in the Bay of Fundy, it involves no numerical assumption as to the friction coefficient. Another perturbation of M_2 at St. John and at Bombay is a secular change of amplitude, ascribed to possible changes in the sand- and mud-banks near the ports.

Carbohydrate Metabolism.

THE breakdown of the carbohydrates found in the body, namely, glycogen and glucose, resulting in their final oxidation into carbon dioxide and water and the liberation of the energy stored in their molecules, takes place by stages, the details of which are still imperfectly known It appears probable that a compound of glucose with phosphoric acid forms an intermediate stage in the conversion of glycogen into glucose, while lactic and pyruvic acids are intermediate products in the conversion of the glucose into carbon dioxide. In the case of striped muscle, the process, as far as the formation of lactic acid, is reversible (Emden, Meyerhof, etc.). Now although the monosaccharides formed in the course of digestion are absorbed and converted into glycogen in the liver, in the reverse process only glucose is produced, suggesting that this sugar has some peculiarity of structure which enables the cells of the body to utilise it, in preference to the others; enzymes are probably concerned in the process, and one of the characteristics of their action is their specificity

Fresh light has been thrown on this subject by the work of Herring, Irvine and Macleod (*Biochem. Jour*, 1924, vol. 18, p. 1023), who have used insulin as a key to the structure which the sugar must possess if it is to be utilised The insulin was injected into mice, and the efficiency of various sugars and other closely related substances in curing the convulsions thus produced determined Glucose and mannose cured the animals completely, but fructose and galactose produced only a temporary improvement Maltose, however, was nearly as efficient as glucose, but somewhat slower in its action None of the other substances tried, including substituted reducing sugars and glucosidic compounds, had any effect Analysis of the results shows that the sugar must possess the following formula,

in which X or Y represents the reducing group The cells of the body are, therefore, only fitted to deal with a sugar of this general type, all other carbohydrates being converted into it by their appropriate enzymes, either directly or after synthesis into glycogen.

Working on quite different lines, Kay and Robison and their co-workers have investigated the properties and functions of the compounds of glucose with phosphoric acid (*Biochem. Jour.*, 1924, vol 18, pp. 1133, 1139, 1152, 1161). Two of these compounds are described, a hexosemonophosphate and a hexosediphosphate, the phosphoric acid being combined with a different group of the sugar in each case. Both compounds are probably present in the blood. An investigation of the distribution in the body of the ferments which act upon them shows that the diphosphate is hydrolysed by an enzyme present chiefly in muscle and blood, while the monophosphate is acted on by an enzyme which can be extracted from bone and ossifying cartilage. In fact, it is suggested that the latter compound is the form in which phosphorus is supplied to the bone in ossification. The injection of insulin increases the amount of the organic phosphoric esters in the blood and muscles, and it is extremely probable that it is the hexosephosphates which are thus affected In this case the fall in the blood sugar after insulin may be connected with the formation of these esters, since it appears that the sugar disappearing is not all oxidised, nor is it converted into fat (*v.* Burn and Dale, *Jour Physiol*, 1924, vol 59, p 164). The formation of a phosphoric ester would, however, be probably only a step in the reversible reaction, glycogen $\rightleftarrows$ glucose The actual direction in which the reaction proceeds depends in all probability on the amount of glycogen in the body in the well-fed animal, the glycogen present is broken down, in the diabetic organism, the reverse process occurs and glycogen appears in the liver

The phosphorus for the synthesis of the ester comes in the first place from the inorganic phosphate of the blood, with the result that less is left available for excretion by the kidney in the urine Sokhey and Allan (*Biochem Jour.*, 1924, vol 18, p 1170), confirming other investigators, have found that dogs after large doses of insulin excrete less inorganic phosphate in the urine during a period of six hours or so the total output for the day is, however, definitely increased, suggesting that some of the newly formed esters are broken down later on The nitrogen excretion is raised simultaneously with the fall in inorganic phosphate. possibly some of the phosphorus required comes from organic compounds which also contain nitrogen Sugar *per os*, on the other hand, while diminishing the inorganic phosphorus of the blood and urine temporarily, does not cause any increased total output of this element in the 24 hours at the same time it lowers the nitrogen excretion by taking the place of some of the protein previously oxidised It appears then that, with excess of sugar in the blood, more of the esters are formed at the expense of the inorganic phosphorus, but that, although the subsequent oxidation is sufficient to reduce the nitrogen excretion by sparing the destruction of protein, it is not enough to raise appreciably the excretion of phosphorus in the urine; the sugar is probably oxidised directly without previous synthesis to glycogen Insulin, however, causes a great increase in the formation of the esters, the phosphorus coming both from inorganic phosphates and also from bodies which contain nitrogen as well as phosphorus in their molecules. The glucose necessary is obtained from that circulating in the body fluids, but in the normal animal an additional source is provided by the reserve glycogen of the liver and muscles, the breakdown of the latter would produce an excess of free phosphorus, which would appear in the urine.

A somewhat different reaction is to be expected from feeding sugar and injecting insulin: glucose alone will not raise the total metabolism to any appreciable extent, while insulin, under certain conditions, will do so by increasing the carbohydrate oxidised, without at the same time reducing the protein broken down: in the normal animal, a limit is probably set to the amount of carbohydrate catabolised at any moment by the amount of insulin available It seems justifiable to draw the general conclusion that insulin acts by assisting the reversible reaction glycogen $\rightleftarrows$ phosphoric ester $\rightleftarrows$ glucose, by causing the production of the ester; the direction in which the reaction proceeds thereafter depends on the amounts of the various interacting substances present at the moment.

Nature and Origin of Coco-Nut Pearls.[1]

By Dr. F. W. T. HUNGER.

IN the endosperm cavity of the seed of *Cocos nucifera* a local calcareous formation is sometimes found to occur, to which the name of "cocos-pearl" has been given, and which must be looked upon as a highly remarkable and very rare occurrence.[2] Such a cocos-pearl has usually the form of a pear, or egg, sometimes it is almost spherical and has a smooth surface, as a rule of a milky-white colour. Its chemical composition corresponds somewhat to that of the oyster-pearl, from which it differs in appearance, however, by the lack of the pearly sheen.

Rumphius was the first to describe this calcareous formation as "calappites,"[3] and for more than a century after him nothing was heard of this condition, until at the meeting of the Boston Society of Natural History on February 1, 1860,[4] Mr. Fred. T. Bush presented a specimen of this cocos-pearl for chemical and microscopical examination. The research was entrusted to Dr. Bacon, who submitted his report on the subject at the meeting of the same Society on May 16, 1860.[5]

In 1866, Dr. Riedel, ex-Resident of Menado, reported having found a pearl in a coco-nut he opened.[6] This was the first report by an eye-witness who had actually seen such a thing, apart from the many stories told by natives about it.

Contrary to the statement of Bush to the effect that cocos-pearls "are said to be found free within the cavity of the coco-nut," Skeat[7] reported in 1900 that they are "usually, if not always, found in the open eye or orifice at the base of the cocoa-nut."

On my last voyage to the East Indies for purposes of study, I resolved to endeavour to find out something further about the cocos-pearl and if possible solve the problem of its formation. At the same time I realised the utter futility of going to look for cocos-pearls in the tropics, on account of their extremely rare occurrence. In proof of this it may be mentioned that on a coco-nut estate, where approximately three million nuts have been opened annually for years, no such pearl has ever been found, although stories about them have led to their existence being suspected.

I therefore directed my research to gathering as many authentic data as possible. On one of my voyages I met a native of British India who possessed a very fine cocos-pearl. According to his own account, he had seen with his own eyes this specimen inside an opened coco-nut which had been brought to him from Madras. He assured me that his pearl had been attached to the kernel of the coco-nut and exactly at the place where, in germination, the cotyledon forms a haustorium.

Later on I also met with an Arab on whose coco-nut plantation in South Borneo a coco-nut had been gathered which, on being opened, proved to contain a pearl attached to the inside of it. He had dislodged the pearl from the kernel of the nut with his own hand. In this case also the pearl had been attached at exactly the same place as in the case first mentioned.

These two corroborative declarations of eye-witnesses, who had both seen a cocos-pearl still attached inside an opened coco-nut, furnished me with a preliminary guiding-thread and led me to suppose that the spot which they indicated would probably be the normal point of attachment of such a cocos-pearl.

The normal germination process of the coco-nut begins by an enlargement of the embryo, whereby the cotyledon commences to grow inwards to an absorbing organ (haustorium), and thereby comes to protrude outside the endosperm and into the central cavity. Simultaneously with this, the plumule grows out and, breaking through the membranous operculum of the germinating pore, it pushes its way out through the hard shell.

Proceeding from the provisional determination of the place of attachment of the cocos-pearl, the following hypothesis could now be formed. Given that the germination, being in progress, is stopped by some cause or other, thus preventing the further development of the haustorium, it is conceivable that the haustorium in this state might become encrusted by the influence of the coco-nut milk, and that from this the completely petrified cocos-pearl would gradually be formed.

It was now necessary to find the reason for any such check in the process of germination and the accompanying solidification of the haustorium.

At the side where the coco-nut has been attached to the stalk, three thin spots, so-called germinating pores, or "eyes," can be seen in the hard inner shell of the fruit. As a rule one of these holes, the so-called "porus pervius," is closed by a membrane, whereas the two other, the so-called "pori cæci," are furnished with a hard tegument. In germination, the plumule pushes its way out through the porus pervius.

By way of exception there may be, instead of three, two germinating pores, namely, one porus pervius and one porus cæcus, and only very rarely will there be only a porus pervius with both pori cæci entirely absent. Nevertheless, a coco-nut of this description can germinate in the usual way. It is a different case, however, when there is not even a porus pervius, the base of the inner shell showing no germinating pore at all, as occurs in extremely rare cases. Such a coco-nut is known in the Malay language as a "kĕlapa boeta," or "klâpâ boentĕt" in Javanese, which signifies a "blind coco-nut."

As remarked above, a coco-nut without germinating pores is a very great rarity, for which reason they are regarded by the Mohammedans as sacred. The "kĕlapa boeta" is a talisman (*tjimat*) *par excellence*, and consequently it is difficult to obtain a specimen.

This meeting with the *kĕlapa boeta* furnished me with an example of the way in which normal germination is rendered impossible in Nature, and I did my utmost to procure some specimens. I finally succeeded in collecting eight unopened "blind" coco-nuts from the East Indian Archipelago. Most of the specimens were very old nuts; some, according to their owners, had been preserved for scores of years as family heirlooms.

The first four "boetas" which I opened produced nothing, but in the fifth I found a really beautiful pearl still attached to the kernel; the next two produced negative results again, and the eighth specimen I have kept unopened.

The nut which had contained the pearl had been gathered but a short time before, and the endosperm in it was quite normal, whereas in the other nuts the kernel was either very much dried up or had even partly become a mass of brown powder. The

pearl was attached without the least trace of a stalk, being merely embedded in the endosperm, and was quite easy to remove from the kernel. It lay exactly at the base of the nut, just under the spot where the germinating pores ought to have been, and thus agreed completely with the indications as given above.

This discovery, in my opinion, warrants the inference that the cocos-pearl actually represents a calcified haustorium, which has been retained in the nut after the primary germination was checked, owing to the plumule not being able to get through the shell on account of the absence of the porus pervius. As the inner shell of the *kĕlapa boeta* remains hermetically closed, the newly formed haustorium becomes encrusted under the influence of the coco-nut milk with calcium salts, although it still remains unexplained why the cocos-pearl consists almost entirely of calcium carbonate, while neither the cocos-kernel nor the coco-nut milk contains this carbonate.

The belief that a *kĕlapa boeta* invariably contains a cocos-pearl was sufficiently disproved by my experience, that of seven specimens, only *one* such formation was found in a "blind" coco-nut. On the other hand, it is probable, in my opinion, that it will be principally (or exclusively?) the *kĕlapa boeta* that contains the cocos-pearl

Annual Meeting of the Mathematical Association.

THE annual meeting of the Mathematical Association was held at the London Day Training College on January 5 and 6. The report of the Council showed that the number of members has increased to 1019, in addition to about 500 associates connected with local branches.

The presidential address was delivered by Prof G. H. Hardy, the subject being "What is Geometry?" Prof. Hardy suggested that the time has come to consider what the subject taught in schools under the name of geometry really comprises It appears to be a mixture, partly an investigation of actual space-relations, based on intuition, partly a system of pure geometry, based on axioms But neither of these subjects is self-contained. Even the so-called projective geometry is not true projective geometry but is based on ideas of geometrical magnitude While recognising that the early teaching of geometry must be a compromise, and that the Association has done very good work in improving it, he thought that an effort might now be made to introduce into schools a more logical study of modern systems of pure geometry

Prof H. Levy gave an address on "The Mathematical Laboratory; its Scope and Function." He said that mathematics is not merely the handmaid of science Mathematical methods based on logical proof are not sufficient for modern needs the methods must be developed so as to meet the requirements of technology—of aeronautics, of biology, of industry He gave an account of the work done at the mathematical laboratory of the Imperial College of Science and Technology, S. Kensington The work, fundamentally, is experimental Any instruments available may be used, and the traditional restriction to rule and compasses is abolished Absolute accuracy is not regarded as essential, and graphical methods, giving results within about 0·5 per cent, are found to be sufficient. The problems to be solved are engineers' problems, not the mathematician's conception of engineers' problems. Differential equations are solved by approximation, by differentiation, etc., and their mathematical treatment in the lecture-room is followed by graphical treatment in the laboratory. The calculation of infinite series, and their differentiation, gives ideas of convergence and divergence of series, and a good deal that is of value can be derived from cases in which series obtained by graphical methods give incorrect numerical results in consequence of the series being divergent. Importance is attached to the study of cases in which different problems lead to the same mathematical equation. In the discussion on the paper, it was suggested that in a school the cost of equipment of a mathematical laboratory might be prohibitive; but Prof. Levy pointed out that, as great accuracy is not essential, second-hand instruments are usually quite good enough.

A discussion on the teaching of arithmetic in schools was opened by Prof J E. A. Steggall, who suggested that more attention might be given to the study of the properties of numbers, and that, in the earlier stages, children might concentrate on the study of some particular table, such as the table of measures of length The discussion raised some interesting points as to method, and questions as to the psychology of the pupil Prof Steggall, in replying, expressed his disapproval of the teaching of anything that could not be understood.

There was some discussion of the recent report (of the Association) on "The Teaching of Geometry in Schools" Prof. M J M. Hill dealt with various methods of arriving at the properties of parallel lines.

Mr A Buxton communicated a note on the treatment of a certain problem in optics by means of Bessel functions.

Dr. H B. Heywood contributed a thoughtful paper on the reform of university mathematics. In foreign universities, courses are given in subjects of which students in Great Britain have practically no knowledge The whole of our mathematical teaching in universities, even more than in schools, is dominated by examination requirements, and no reform is possible until the examination system is modified. Some suggestions that Dr Heywood made were that it is not necessary to examine over the whole field, but that an intensive study of some part should be allowed, that theses, followed by oral examination, should be encouraged, that more importance should be attached to reports by teachers, and that over the whole range the study should be less academic There is no border-line between mathematics and physics, and there is no need for physics to be made fictitious when it becomes a subject for mathematical treatment The extent of ground common to mathematics and physics should be investigated The decision as to the content of a mathematical course must be made on the basis of vitality, and this requires a purposeful study of the whole domain of mathematics, to see what portions are alive and growing Such a study would show what reforms are needed In the discussion, Prof. E. W Hobson agreed that reform must work downwards from the universities, but he was inclined to dissent, at any rate as regards Cambridge, from the view that the universities are more dominated than the schools by examination requirements Prof. Hardy stated that he considered reform to be impossible without destruction, and said he would like to begin by destroying the mathematical tripos.

During the luncheon interval, on the second day, there was a very interesting exhibition of pieces of apparatus, designed by Mr. E. J Atkinson, by Mr. C. V. Durell, and by Mr. D. F Ferguson, for use in connexion with the teaching of mechanics.

University and Educational Intelligence.

CAMBRIDGE.—The Sedgwick Prize has been awarded to Mr. H Hamshaw Thomas, fellow of Downing College.

Mr. C. T. R Wilson, fellow of Sidney Sussex College, university reader in electrical meteorology, and observer in meteorological physics at the Solar Physics Observatory, has been elected to the Jacksonian professorship of natural philosophy

OXFORD.—It is expected that in the course of the present term, which began on January 19, much progress will be made with the final settlement of College Statutes, which are now before the Universities Commission

The Romanes Lecture for 1925 will be delivered by Sir William Bragg in the Sheldonian Theatre on Wednesday, May 20, at 5 30 P M Sir William's lecture will be on "The Crystalline State."

PROF ANDREAS VON ANTROPOFF, of the Technische Hochschule, Karlsruhe, has been offered the chair of physical chemistry at the Chemical Institute in the University of Bonn.

ACCORDING to a message from the Toronto correspondent of the *Times*, the will of the late Mr D A Dunlap includes bequests of 50,000*l* to Victoria University, one of the constituent colleges of the University of Toronto, and 20,000*l* to the University of Toronto for medical resources.

MR F J HARLOW has been appointed principal of the Wigan and District Mining and Technical College, in succession to Mr S. C Laws, who has become principal of the Northampton Polytechnic Institute, London Mr Harlow has been, for the past four years, principal of the Blackburn Municipal Technical College He is a B Sc (Physics, 1st class honours) of the University of London and an associate of the Royal College of Science, and he also holds the diploma (by research) of the Imperial College of Science and Technology

PROF H E ARMSTRONG, addressing the students of the Stoke-on-Trent evening schools on January 8, protested vigorously against the unpractical character of the teaching in English schools "School, in the main, is but the means of keeping children occupied and ignorant up to a certain age, there is no conscious logical method behind it" Hence it is that our commercial men and leaders of industry are ill-informed, and manual dexterity is going from us owing to our slavish use of machinery To prate of the value of the study of the humanities while we welter in ignorance of the world about us, and the public remains incapable of appreciating and using the vast achievement of scientific workers for its intellectual development, Prof Armstrong stigmatised as "pure Pecksniffery" If the Potteries are to be capable of meeting the coming competition of Germany, the type of teacher required is the enthusiast for "Beauty in its many forms, one of which, and the greatest, is Truth," with power to kindle the imagination of pupils and other teachers Thence will come capacity for producing work of beauty and value which will therefore attract The number of students enrolled for the current session in the Stoke-on-Trent evening schools reaches the respectable total of 5700, including more than a thousand in the Art Schools and 600 in the Central School of Science and Technology, which, by the way, is extending its pottery course, for students who have completed a secondary school curriculum, from three to four years. It has a separately organised research department, with a staff of eight investigators.

Early Science at the Royal Society.

January 25, 1664/5. In order to see, whether the compression of the air caused the extinction of fire, there was put a lamp into the condensing engine; and a great quantity of air being crowded into it, it was found, that the lamp burnt in that compressed air about 15 minutes, whereas in the uncompressed air in the same engine, it burnt not above 3 minutes.—It was ordered that at the next meeting an experiment should be made, of filling a vessel with smoke, to see, whether a candle put into it would burn as long therein, as it would do in the same air without smoke.

1671/2. Mr Oldenburg read a letter from Mr. Newton from Cambridge, of a way of preparing a fit metalline matter for reflecting concaves "I desire," he says, "that in your next letter you would inform me, for what time the Society continue their weekly meetings; because if they continue them for any time, I am purposing them, to be considered of and examined, an account of a philosophical discovery, which induced me to the making of [my] telescope, and I doubt not but will prove much more grateful than the communication of that instrument, being, in my judgment, the oddest, if not the most considerable detection, which hath hitherto been made in the operations of nature"

January 26, 1670/1. Mr Oldenburg produced some of the rock-salt lately digged up in Cheshire, mentioning that the workmen had bored three yards into it That an hot fire makes the salt crack and fly like bags of kelp That hot water dissolves it speedily, and cold slowly that being pulverised it is a very strange salt, and the brown, that is free from mixture full as sharp as the white.

January 27, 1663/4. Ordered—That the president move this day the Society to appoint a committee of physicians, who are fellows of the Society, constantly to consider, what is necessary to be prosecuted in anatomy and surgery—That the porter be allowed three pounds a year for his constant attendance, to be paid him quarterly

1669/70. Mr. Oldenburg read the paper concerning Cassini's pretended new method, geometrical and direct, of finding the apogees and excentricities of the motion of the planets, after which he moved, that it might be inquired into, whether the like method had not been already found out in England. Whereupon Mr Mercator, having considered this matter in private, produced a paper of his, which shewed, that this very thing was founded upon what Dr. Seth Ward, now lord bishop of Salisbury, had demonstrated in his "Astronomia geometrica" published in 1656. This paper was read, and being found to be the demonstration of this alleged invention of Cassini, printed as such in the French *Journal des Sçavans* of September 2, 1669, it was thought proper, that the narrative of the truth of this matter should be published in the *Philosophical Transactions*.

January 28, 1662/3. Mr Hooke made the experiment of shutting up in an oblong glass a burning lamp and a chick; and the lamp went out within two minutes, the chick remaining alive, and lively enough.—Mr. Matthew Wren gave an account of a carp kept a whole week in a cellar out of the water, and fed with moistened bread, wetting the gills of it once or twice a day Dr Croune was put in mind to make this experiment, as he had formerly promised.

1668/9. The copies of Mons. Huygen's theory of motion were delivered, one to Dr. Wren, and another to Mr. Colwall.

January 30, 1660/1. Being the day of fast and humiliation for the death of King Charles I. there was no meeting of the Society.

Societies and Academies.

LONDON.

Royal Society, January 15.—Sir Charles **Sherrington** and E G T **Liddell** Further observations on myotatic reflexes The myotatic reflex of the knee-extensor obtains after pre-collicular as well as after inter-collicular transection The reflex retains tonic character after exclusion of the otic labyrinths Stretch of the knee-flexors also yields a myotatic reflex, a main action of which is the depression by inhibition of the myotatic reflex of their antagonist, the knee-extensor The reflex relaxation of the knee-extensor thus obtained is not changed into contraction by administration of strychnine —A V **Hill**, C N H **Long**, and H **Lupton** Muscular exercise, lactic acid, and the supply and utilisation of oxygen An attempt is made to apply to the case of muscular exercise in man the principles discovered in the last seventeen years by the physical and chemical investigation of activity in the isolated frog's muscle Part I. summarises the investigations, especially such as refer to the recovery process by which lactic acid, liberated during exercise, is removed in the presence of oxygen afterwards In Part II. is described the method of estimating lactic acid in human blood Part III is a description of the lactic acid changes which occur in human blood, during and after exercise, with an account of their effect on the respiratory quotient Part IV describes methods of studying the respiratory exchanges in man, under the rapidly altering conditions which obtain at the beginning and end of exercise. Part V is an account of the recovery process, in which oxygen is used and the lactic acid produced during activity is restored as the glycogen from which it arose In Part VI a discussion is given of the "oxygen debt" existing at the end of exercise, and of the muscle as an "accumulator of energy" Part VII. describes the relation between the rate of oxygen intake and the intensity of exercise Considerably increased amounts of oxygen can be taken in when breathing gas mixtures rich in oxygen. In Part VIII curves are given relating the "oxygen requirement" to the severity of various types of exertion —A. P **Chattock**. The physics of incubation. Daily cooling appears to be unnecessary, but an improvement in the hatching of more than 11 per cent is indicated if the usual twice-a-day turning is increased to four times at equal intervals By means of specially designed hygrometers, values of the humidity under hens have been obtained, very little improvement resulted from raising the humidity in incubators to the hen's nest value (20 mm water-vapour pressure at the centre) On the principle that the water vapour and carbon dioxide which escape from the eggs during incubation must both leave the nest by the same paths, the ventilation in a hen's nest may be estimated The value obtained is equivalent to the passage through the nest of 3·2 cubic feet of air per hour per 50 eggs; and is several times smaller than the ventilating air flow in typical "hot air" and "tank" incubators.—J. F **Fulton**. (1) The influence of tension upon the electrical responses of muscle to repetitive stimuli. Simultaneous mechanical and electrical records of short, maximal, tetanic responses of intact skeletal muscle (gastrocnemius and sartorius; frog) have shown that the *size* of the successive electrical responses varies in isometric contraction with the tension developed, and in isotonic records with the work done Tension *per se* rather than length of fibre controls the size of the action current. The mechanism which determines the size of the action current probably also controls the energy liberation within the fibre (2) The relation between the durations of the isometric twitch and of the after-action of tetanus The end of the plateau of short tetanic responses is characterised by an "angle" similar to that of the twitch The duration of the after-action as measured from the beginning of the last electrical response of the tetanus to the "angle" is, in short tetani, invariably less than the duration of the twitch. The ratio of these two durations is approximately the same as that of the size of the corresponding action currents. The terminal "angle" of long tetani is less precise than in short, and is also less precise at high initial tensions than at low tensions These modifications of the "angle" may be taken as evidence of slight fatigue—a less prompt "neutralisation" of the activating ions (3) Some observations upon the electrical responses and shape of the isometric twitch of skeletal muscle. Isometric twitches of the intact gastrocnemius of frogs, when recorded with a myograph of high natural frequency, have a flat top which terminates with sufficient abruptness to form on the linear record a clearly defined "angle." Any factor tending to produce fatigue, obscures the "angle" From the shape of the isometric twitch it has been inferred that the "fundamental" process of contraction is rectangular in shape, the "angle" representing the point at which it ends, and the curve of relaxation representing the viscous return of the muscle to its resting shape.

PARIS.

Academy of Sciences, December 15 —M Guillaume Bigourdan in the chair —P **Villard** The construction of electro-magnets Comparison of results obtained with differently shaped pole pieces, one cylindrical the other conical —Ch **Depéret** The classification of the older Palæolithic from the historical and geological points of view The palæolithic strata known as the Chellean consists of deposits of two different ages One of these is older than the Chelles gravels, and for this the term pre-Chellean is proposed The difference of age is shown both by the fauna and by the worked implements —Ch. **Depéret**, Fabien **Arcelin**, and Lucien **Mayet** New discoveries in the prehistoric deposit of Solutré (Saône-et-Loire) Following up the discoveries of human remains made in 1923, excavations near the same spot have revealed two more complete skeletons of Cro-Magnon type The excavations of 1924 at Solutré have proved the existence, in regular superposition, of a series of levels containing graves, ranging from the Aurignacian epoch up to historic times.—Maurice **Lugeon** River erosion. Example of the Rio Uruguay.—C **Sauvageau**. The curious development of *Castagnea Zosteræ* —Paul **Montel**. The wave-lengths and intensities of 253 lines in the

region 1855 Å and 1505 Å are given: about half of these are new.—Alb. **Colson**: The displacement of the maximum of solubility and the existence of constant solubilities.—E. **Carrière** and E. **Vilon**: Experimental study of the action of sulphuric acid on calcium oxalate. After proof of the existence of an equilibrium, the influence of each of the variables, temperature, concentration of calcium oxalate and sulphuric acid, and excess of sulphuric acid was separately determined, the results being shown in the form of curves.—Claude **Fromageot**: Adsorption and cataphoresis.—P. **Lebeau** and P. **Marmasse**: The thermal fractionation of the gaseous products from the carbonisation of the structural constituents of bituminous coals. Fusain, durain, clairain, and vitrain from an English coal, and vitrain and durain from a French coal have been submitted to the method of fractional carbonisation described in an earlier paper (*Comptes rendus*, 177, p. 319). The results are shown graphically and analyses of the total gas obtained given. The composition of the gases obtained are very similar and they do not differ much from the gas obtained by the carbonisation of the original coal. The two vitrains, however, show a higher percentage of methane.—G. **Saurat**. The quaternary formation of Syrte minor.—Pierre **Lamare**: The presence of granites in the valleys of Baztan and Bertizarana (Haute-Bidassoa) and their tectonic significance.—G. **Mouret**: The geology of the Plateau of Aigurande and the dislocations of the neighbourhood of Neris (Allier).—Sabba **Stefanescu**: The presence of *Elephas planifrons* and of three mutations of *Elephas antiquus* in the geological layers of Roumania.—H. **Hérissey**: The presence of a glucoside in *Baillonia spicata* capable of being hydrolysed by emulsin, and the products of hydrolysis of this glucoside. The glucoside was not isolated, but from its hydrolysis by emulsin, *d*-glucose and a lactone, named baillonigenol, were isolated in a pure and crystallised condition.—P. **Freundler**: The conditions of the stabilisation of iodine in *L. flexicaulis*. The initial amount of iodine in these algæ may be preserved in three ways: increasing the saline concentration, heating in closed vessels at 110° C., or by complete desiccation at 105° C.—L. **Grigoraki**: Contribution to the study of Dermatophytes.—A. **Maige**: The evolution of amylogen excitability of the plastids in cells with starch reserves.—Maurice **Nicloux** and A. **Yovanovitch**: The fixation of chloroform by the central nervous system and the peripheral nerves. The method previously worked out for the determination of minute quantities (0·5 mgm. to 1 mgm.) of chloroform in blood and the tissues has been applied to the study of the amounts of chloroform fixed by the nerves after anæsthesia. The peripheral nerves, such as the central nervous system, fix the largest quantities of chloroform.—R. **Herpin**: The swarming and development of Eunice and Syllis.—Armand **Dehorne**. The histo-physiology of the intestinal cells of Ascaris of the horse and of the turtle.—Ch. **Pérard**: Researches on the destruction of the oocysts of Coccidia. The oocysts of *E. perforans* and *E. stiedæ* have been submitted to the actions of solution of various disinfectants, including formol, phenol, corrosive sublimate, and hypochlorites, and are not destroyed after 24 hours' exposure to these media, and in fact appear to develop better after such treatment. On the other hand, these organisms are very sensitive to drying or to heat and this is recommended for their destruction.—Henri **Stassano**: The mode of action of heat on the lactic ferments in the pasteurisation of milk. Three methods were tested: maintenance at 95° C. for two minutes, at 63° C. for 25 minutes, and in thin layers at 75° C. for 8 seconds. Some lactic ferments survive all three methods of pasteurisation, but the third method proved relatively the most efficient.—P. **Lemay** and L. **Jaloustre**: The comparative action of bismuth on staphylococcus, streptococcus, and the Coli bacillus. The staphylococcus is most sensitive to the action of bismuth salts.—H. **Labbé** and **Lavagna**: The action of acetoacetic acid on the nitrogen nutrition.—W. **Kopaczewski**: Surface tension and the cancer problem. It is proved by experiment that the development of cancer is accompanied by a diminution of the surface tension of the serum and blood plasma.—Jean **Saidman**. The absorption of ultra-violet rays by the skin and its therapeutical applications.—**Kohn-Abrest**: The index of toxicity and the utilisation of petrol in motor-cars. The ratio CO/CO_2 in the exhaust gases of a petrol motor is defined as the index of toxicity. Some determinations of this index are given, based on analyses of the exhaust gases of a motor-car working under different conditions.

Calcutta

Asiatic Society of Bengal, December 3.—C. **Dover**: Further notes on the Indian diplopterous wasps. The subject is discussed from the faunistic point of view, and is based on a study of the Vespidæ in the British Museum; it is an attempt to settle the systematic position of various Indian forms.—Satya Churn **Law**: Kālidāsa and the migration of birds, No. 2. The migratory Hansas and Raj-hansas in Kālidāsa's works.—H. **Beveridge**: On Tamerlane. A review of the information in our possession about "the terrible Vulcan of Samarcand".—Maulavi 'Abdu'l **Wali**: Notes on the archæological remains in Bengal. The antiquities dealt with are situated in Burdwan, Murshidabad, Midnapur, Narayanganj, Birbhum, Aurangabad and other places.—Hirendra Lal Sen **Gupta**. A short history of the Madhyamika philosophy.—Hari Krishna **Deb**. "Ant-gold" and the Kautilīya Arthasāstra. The story of the so-called gold-digging "ants," in the sandy regions of Dardistan, related by Herodotus and later writers, is referred to in a passage in the Kautilīya. Cunningham's conjecture that these "ants" were some kind of marmots is confirmed. Incidentally, it is suggested that the "griffins" alleged to guard the gold dug up by "ants" may have been some variety of ant-eaters.—Hari Krishna **Deb**: (1) The Kautilīya Arthasāstra on the three classes of invaders. Invaders are classified in the Kautilīya as *dharma-vijayinah*, *lobha-vijayinah* and *asura-vijayinah*. The pre-Asokan date of this classification being shown, the inference is that India was already familiar with the Assyrian (asura) mode of invasion.—(2) The Kautilīya Arthasāstra on forms of government. The Kautilīya presents us with a threefold classification of forms of government, here analysed, namely, *rājya*, *dvairājya* and *vairājya*, corresponding respectively to government by one, by two or by the multitude. The Kautilīya's discussions contain helpful hints for a reconstruction of pre-Mauryan political and constitutional history.—Chhote Lal **Jain**: A bibliography of literature relating to Jainism, mainly from 1907 to 1924.

Rome

Reale Accademia dei Lincei: Communications received during the vacation, 1924.—T. **Levi-Civita**: Exact determination of periodic irrotational waves in deep water.—E. **Carano**: Observations on the mechanism of division of the mother-cell of the embryo sac in apogamous plants.—Bonaparte **Colombo**: Study of the equations

$$\frac{\partial^2 z}{\partial x^2 \partial y} + \frac{\partial^2 z}{\partial x \partial y^2} = f(x, y, z, p, q, r, s, t)$$

and

$$\left(\frac{\partial}{\partial x} + \lambda_n \frac{\partial}{\partial y}\right)\left(\frac{\partial}{\partial x} + \lambda_{n-1} \frac{\partial}{\partial y}\right) \cdots \left(\frac{\partial}{\partial x} + \lambda_2 \frac{\partial}{\partial y}\right)\left(\frac{\partial z}{\partial x} + \lambda_1 \frac{\partial z}{\partial y}\right) = F(x, y).$$

—Francesco **Sbrana**: Certain integral equations.—Washington Del **Regno**: Photo-electric emission of selenium. No difference is detectable between the emission from selenium in the dark and in the light, the free electrons thus appearing to play no part in the phenomenon. The purely electronic character of the conductivity of selenium under the influence of light is upheld.—Bernardo **Oddo**: Diindylmethane.—Gaetano **Charrier** and Alessandro **Beretta**: Action of nitrosobenzene on *o*-nitroaniline. The product of this action is *o*-nitro-*p*′-nitrosodiphenylamine.—Gustavo **Cumin**. Geological notes on the Istrian mountain region. I. Soils.—Enrico **Fossa-Mancini**. Tertiary strata in the neighbourhood of Orosei (Eastern Sardinia).—Ugo **Panichi**. The specific gravity of minerals and crystallised chemical compounds.—G. **Micatovich**. Experiments confirming the statolytic theory.—A. **Spartà**: Contribution to the knowledge of larval development in *Uraleptus Maraldii*.—Risso.—Livia **Garofolini**. Development of the chromaffine system and appearance of the chromoreaction in *Triton cristatus*.—Luisa **Volterra**. Variability of pelagic Dafnias in Lakes Albano and Nemi: *Daphnia longispina*.—Ugo **Banderati**. Action of alcohols on the sensory-motor cortical centres of the dog.—Mario **Ercole**. Contribution to the knowledge of the rhythm of renal secretion.—Carlo **Mannella**: Action of strychnine on the survival of the central preparation.—Carlo **Petacci**. Action of ethyl alcohol on the survival of the central preparation.—Palmira **Tavolaro**. Direct action of strychnine and various alcohols on the central preparation.—Oliviero **Olivo**. Commencement of the functional capacity of the contractile tissues in the embryo of the hen, in relation to their structural and morphological differentiation. I.: Functional and morphological differentiation of the cardiac embryo.—Gabriella **Armellini-Conti** and Giuseppe **Armellini**: Investigations on the variation of the luminous intensity of the moon during the total eclipse of August 14, 1924. From the moment at which the moon entered the earth's shadow until the eclipse became total, the total luminous intensity of the moon varied approximately according to a parabolic law. When the moon, entirely in the penumbra, began to enter the umbra, the intensity was nine-tenths of that exhibited by the full moon, whilst the intensity of the totally-eclipsed moon was about one-fortieth of that of the full moon.—F. **Zambonini** and G. **Carobbi**. Contribution to the study of the isomorphous relationships between compounds of beryllium and those of magnesium. In compounds of simple structure, beryllium and magnesium are probably not isomorphogenic except in very special cases, but mixed crystals of the double nitrate of magnesium and lanthanum with that of beryllium and lanthanum containing so much as 18 per cent. of the latter are obtainable.—L. **Sabbatani**: Pharmacological investigations on iron. VI.: Colloidal ferrous sulphide prepared in the presence of sugar. A preparation has been obtained which is much less toxic than that made in the presence of gelatin and is fixed more exactly and immediately, and almost exclusively in the liver and spleen. Such preparations produce pharmacological effects only as the result of chemical changes, which are rapid and profound with colloids of high degrees of dispersivity and stability, but slow and slight if the degrees of dispersivity and stability are low.—B. **Longo**: Further results on the sowing of the wild fig.—A. **Russo**. Different constitutions of the two pure gametes in *Cryptochilum echini* Maupas, resulting from the analysis of the nuclear successions, and the prevalence of the globuliform micronucleus.—Francesco **Sbrana**: Levi-Civita's parallelism for a surface of ordinary space.—Umberto **Crudeli**: Stationary motions in electronic dynamics.—Enrico **Fermi**: Theory of collisions between atoms and electric corpuscles.—G. **Carobbi**. Double nitrates of metals of the cerium group with copper and with cadmium.—G. **Sani** and V. **Grilli**: Practical notes on the conservation and transformation of nitrogen in stable manure.—Angelo **Bianchi**: Bismuthinite from Crodo, Val d'Ossola, and the crystallographic constants of bismuthinite.—E. **Onorato**: Celestine from Caramanico.—Emanuele **Quercigh**. Celestite from Pietraperzia and from Trabonella (Caltanissetta).—Carmela **Ruiz**: Celestite from Racalmuto (Girgenti).—Roberto **Savelli**. Genetic theory on the "electric mutations" obtained by Alberto Piròvano.—Cesare **Artom**: The species of *Gambusia* acclimatised in Italy (*Gambusia holbrooki* Grd.) in relation to the stability of the character of the gonopodium.—Giulio **Cotronei**. Dimensions reached by *Petromyzon fluviatilis* and the phenomenon of contraction. With this animal, the percentages of the two sexes may be considered identical. The female is larger than the male, and the form living in Southern Europe attains smaller dimensions than that of the north.—Boldrino **Boldrini**. Certain biological reactions encountered in the blood serum of women during and after the lacteal decline. I. Demonstration of a precipitin of human milk serum.—Gaetano **Viale**: Variations of catalysis in the blood on high mountains.—Marcello **Boldrini**. Internal and external measures of certain long bones in man and in woman. I. Volume of the medullary cavity and the phenomena of circulation and respiration.—Oliviero **Olivo**. Commencement of the functional capacity of contractile tissues in the embryo of the chicken in relation to their structural and morphological differentiation. II. Functional and morphological differentiation of the myotome.

Diary of Societies.

SATURDAY, JANUARY 24.

BRITISH MYCOLOGICAL SOCIETY (in Botany Department, University College), at 11 A.M.—Miss E. M. Blackwell: An Outline of the Life History of *Phytophthora Castorum*, Schroet.—H. R. Briton-Jones: The Diseases known as "Bark Canker" and "Die-back" of Fruit Trees.—J. Ramsbottom: Fragmenta Mycologica (II.).—Dr. M. C. Rayner: Sectoring in Cultures of *Phoma radicis Callunæ* Rayn.—E. S. Salmon: The Epidemic Appearance in England in 1924 of a "Downy Mildew" of the Hop.

MONDAY, JANUARY 26.

ROYAL IRISH ACADEMY, at 4.15.

INSTITUTE OF ACTUARIES, at 5.—C. R. V. Coutts: Notes on Life Assurance Investment Policy.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Recent Discoveries of Fossil Man (IV.). Neanderthal Man in Malta. A Review of the Racial Characters of the Inhabitants of Southern Europe in later Pleistocene Times.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—S. W. Melsom and others: Discussion on the National Physical Laboratory and its Work.

SOCIETY OF CHEMICAL INDUSTRY (Yorkshire Section) (at the Great Northern Hotel, Leeds), at 7.15.—The Donnan Equilibrium in Chemical Industry.—Prof. H. M. Dawson: The Donnan Membrane Equilibrium Hypothesis.—W. R. Atkin: The Donnan Equilibrium in the Leather Industry.—J. B. Speakman: The Donnan Equilibrium in the Textile Industry.—Prof. N. M. Comber: The Donnan Equilibrium in Soil Phenomena.

INSTITUTION OF ELECTRICAL ENGINEERS (North-Eastern Centre) (at *Armstrong College*, Newcastle-on-Tyne), at 7.15.—*L.* H. A. Carr: The Use of Induction Regulators in Feeder Circuits.

INSTITUTION OF AUTOMOBILE ENGINEERS (Graduates' Meeting) (at Institution of Mechanical Engineers), at 7.30.

ROYAL SOCIETY OF MEDICINE, at 8.—G. F. Cale Matthews: A Case of Long-standing Insomnia cured by the Extraction of Pulpless Teeth.—L. E. Claremont: The Problem of Pulpless Teeth.

ROYAL SOCIETY OF ARTS, at 8.—V. E. Pullin: Radiological Research—a History (II.) (Cantor Lectures).

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Brig.-Gen. the Hon. C. G. Bruce and Major Northey: Nepal.

MEDICAL SOCIETY OF LONDON, at 8.30.—Prof. A. Castellani: Parenteric Fevers.

TUESDAY, JANUARY 27.

ROYAL DUBLIN SOCIETY (in Royal College of Surgeons, Dublin), at 4.15.—G. Browulee: The Interpretation of certain Empirical Standards in their Application to Irish Butter.—Prof. E. A. Werner: The Decomposition of certain Amino-Acids by Alkaline Hypobromite.

ROYAL SOCIETY OF ARTS (Dominions and Colonies Section), at 4.30.—W. R. Dunlop: Economic Research in Tropical Development, with Special Reference to British Guiana and British Malaya.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Dr. H. R. Hall: The Connexion and Relations of the Prehistoric Greek and Ancient Egyptian Civilisations (I.).

INSTITUTION OF CIVIL ENGINEERS, at 6.—Dr. E. H. Salmon: The Southampton Floating Dock.—F. E. Wentworth Sheilds: Southampton Floating Dock. Subsidiary Works.

INSTITUTION OF AUTOMOBILE ENGINEERS (at Institution of Mechanical Engineers), at 7.—A. E. Berriman: A Review of the Rating Question.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—Sir Alexander B. W. Kennedy: Petra.

INSTITUTION OF AUTOMOBILE ENGINEERS (Coventry Graduates' Meeting) (at Broadgate Café, Coventry), at 7.15.—L. Jefferies: Gearing.

INSTITUTION OF ELECTRICAL ENGINEERS (North Midland Centre) (at Leeds University), at 7.30.—Prof. G. W. O. Howe: World-wide Radio Telegraphy (Faraday Lecture).

INSTITUTION OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND (at 39 Elmbank Crescent, Glasgow), at 7.30.

ILLUMINATING ENGINEERING SOCIETY (at Royal Society of Arts), at 8.—J. W. T. Walsh and others: Discussion on The Effect of Internal Obstructions on the Performance of a Lighting System.

WEDNESDAY, JANUARY 28.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Recent Discoveries of Fossil Man (V.). France and Germany.

INSTITUTION OF AUTOMOBILE ENGINEERS (North of England Section) (at 244 Deansgate, Manchester), at 6.30.—W. D. Williamson: The Respective Spheres of Petrol, Steam, and Electric Commercial Vehicles.

INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (at the Midland Institute, Birmingham), at 7.—Prof. G. W. O. Howe: World-wide Radio Telegraphy (Faraday Lecture).

ROYAL MICROSCOPICAL SOCIETY (Industrial Applications Section), at 7.30.—The Use of the Microscope in the Dairying Industry:—Prof. R. S. Williams: The Microscope of Fundamental Importance to the Industry.—N. Wright: The Structure of the Udder, Normal and Abnormal.—A. T. R. Mattick: The Differentiation of the various Cells found in Milk.—L. J. Meanwell: The Application of the Microscope to the Detection of Tuberculous Infection.—*J. Golding*: Fat Globules.—Miss E. R. Hiscox: The Separation and Identification of Micro-organisms causing Faults in Milk Products.—J. E. Barnard: The Elementary Principles of Microscopical Illumination (2). Self-luminous Objects (Lecture Demonstration).

ROYAL SOCIETY OF ARTS, at 8.—C. A. Baker: The Electrical Equipment of the London County Hall.

INSTITUTION OF CHEMICAL ENGINEERS (at Institution of Mechanical Engineers), at 8.—B. W. Clarke, S. G. M. Ure, and Prof. J. W. Hinchley: Studies in Filtration.

BRITISH PSYCHOLOGICAL SOCIETY (Medical Section) (at Royal Society of Medicine), at 8.30.—Dr. M. D. Eder: Substitution.

THURSDAY, JANUARY 29.

ROYAL SOCIETY, at 4.30.—P. M. S. Blackett: The Ejection of Protons from Nitrogen Nuclei, photographed by the Wilson Method.—R. E. Gibbs: The Variation with Temperature of the Intensity of Reflection of X-Rays from Quartz and its Bearing on the Crystal Structure.—R. W. Gurney: (1) Ionisation by Alpha Particles in Monatomic and Diatomic Gases, (2) The Stopping-Power of Gases for Alpha Particles of Different Velocities.—Dr. W. E. Curtis: The Fulcher Hydrogen Bands.—W. L. Webster: The Magnetic Properties of Iron Crystals.—*To be read in title only*.—A. E. Ingham and J. E. Jones: The Calculation of certain Crystal Potential Constants and on the Cubic Crystal of least Potential Energy.—E. C. Stoner and L. H. Martin: The Absorption of X Rays.—F. H. Schofield: The Thermal and Electrical Conductivities of some Pure Metals.—M. de Sélincourt: The Effect of Temperature on the Anomalous Reflection of Silver.—T. L. Ibbs: Thermal Diffusion Measurements.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Sir William Bragg: The Properties and Structure of Quartz (I.).

SOCIETY OF CHEMICAL INDUSTRY (Glasgow Section) (at 39 Elmbank Crescent, Glasgow), at 7.—Prof. C. H. Desch: Recent Developments in the Cement Industry.

INSTITUTION OF WELDING ENGINEERS (at Caxton Hall, Westminster), at 8.—Sir W. Peter Rylands: The Philosophy of Welding.

ROYAL SOCIETY OF MEDICINE, at 8.30.—Discussion: Radiotherapy and Electrotherapy in Diseases of the Bladder and Prostate.

FRIDAY, JANUARY 30.

ROYAL DUBLIN SOCIETY, at 4.30.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Recent Discoveries of Fossil Man (VI.). Recent Discoveries of Fossil Man in England and their bearing on the Early Distribution of Racial Types in Europe.

INSTITUTION OF MECHANICAL ENGINEERS.—Discussion: Alternatives to the "Clash" Type of Change-Speed Gear for Motor Vehicles.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—P. C. W. King: The Evolution of the Airship.

SOCIETY OF CHEMICAL INDUSTRY (Birmingham and Midland Section) (at Birmingham University), at 7.15.—A. J. Broughall: The Utilisation of Waste Steam.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Middlesbrough Branch) (at Cleveland Scientific and Technical Institute, Middlesbrough), at 7.30.—F. D. Verrill: Shipyard Pneumatic Plant and Pneumatic Riveting.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—E. Ambrose: Notes on High Voltage Electrical Transmission (Lecturette, Slides).

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Prof. J. W. Gregory: The Mountain Structure and Geographical Relations of South-Eastern Asia.

INSTITUTION OF MECHANICAL ENGINEERS (Sheffield Section).

PUBLIC LECTURES.

SATURDAY, JANUARY 24.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—W. J. Perry: Rough Stone Monuments and their Builders.

MONDAY, JANUARY 26.

LONDON SCHOOL OF ECONOMICS AND POLITICAL SCIENCE, at 5.—Dr. E. B. Behrens: Constitution of International Labour Organisation.

UNIVERSITY OF LEEDS AND LEEDS PHILOSOPHICAL AND LITERARY SOCIETY (at Leeds University), at 5.15.—Sir Richard Paget, Bart.: The Nature and Synthetic Production of Human Speech.

KING'S COLLEGE, at 5.30.—C. J. Gadd: Some Results of the Excavations of Ur.

ROYAL SANITARY INSTITUTE, at 5.30.—Prof. H. R. Kenwood: Introductory Lecture to Students in the several Courses of the Institute.

TUESDAY, JANUARY 27.

KING'S COLLEGE, at 5.30.—Rev. Prof. W. R. Matthews: Philosophy and Religion.

UNIVERSITY COLLEGE, at 5.30.—Prof. G. Elliot Smith: The Evolution of Man.

UNIVERSITY OF LEEDS AND LEEDS PHILOSOPHICAL AND LITERARY SOCIETY (at Leeds University), at 8.—Prof. A. Gilligan: The Geology of Yorkshire: The Effects of the Glacial Period.

WEDNESDAY, JANUARY 28.

LONDON SCHOOL OF ECONOMICS AND POLITICAL SCIENCE, at 5.—The Principles of Design as applied to Textiles.

THURSDAY, JANUARY 29.

LONDON SCHOOL OF ECONOMICS AND POLITICAL SCIENCE, at 5.—Dr. H. Hall: The Records of Famine in Mediæval England (as illustrated by the Manorial Rolls of the Bishopric of Winchester).

FRIDAY, JANUARY 30.

UNIVERSITY OF LEEDS AND LEEDS PHILOSOPHICAL AND LITERARY SOCIETY (at Philosophical Hall, Leeds), at 8.—Prof. J. Garstang: The Archæology of Palestine.

SATURDAY, JANUARY 31.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Miss M. A. Murray: The Empire of Egypt.

SATURDAY, JANUARY 31, 1925.

Early Activities of the Royal Society.

DURING the past twelve months NATURE has published, week by week, a column of selected extracts from Dr. Birch's "History of the Royal Society," under the title of "Early Science at the Royal Society." Its commencement was the subject of an explanatory note in the issue of February 9, 1924. The series has run the allotted period, and now some kind of retrospect of the discussions, experiments, and policy of the circle of men who were the promoters of the Royal Society, and of experimental inquiry in general, may be of advantage.

The series comprised the years 1660–87, an interval marking initial, yet fruitful, efforts to establish something that should be permanent in the English commonwealth of knowledge, something that should be shaped out and handed down to others as a reality. The accounts (in brief) of schemes propounded and experiments performed will, it is hoped, have been the means of bringing readers of NATURE into the atmosphere of patient endeavour which animated the founders of the "New Philosophy." We can, all the more readily, picture them forgathering at Gresham College in harmonious conclave and intent. True, as time proceeded, as mind encountered mind, weighty criticisms were offered, whilst dissensions, not quite of a milk-and-water type, arose; notwithstanding such intrusions, through all the same high resolve is maintained, the same sense of original responsibility is apparent. The grip of national conflict was over, perhaps forgotten, and things bespeaking mental awakening held indisputable sway. Harrington's contemptuous comment that they were, in early constitution, an assembly of men who had an excellent faculty of magnifying a louse and diminishing a commonwealth became empty and barren.

Inquiries in the departments of natural history, physiology (as understood), chemistry, medicine, mechanics, and astronomy were actively fostered, the last named especially. The vegetation of plants was frequently the subject of discourse. Evelyn's "Sylva" appeared in 1662. In 1673, Grew's microscopical observations of the texture of a piece of a walnut-tree section were discussed. The history of the silk-worm, in Latin, by Signor Malpighi, was sent in 1668, and ordered to be printed. The operator was directed to try again the feeding of spiders upon one another. In 1669, Robert Hooke (versatile and elusive, yet a veritable Master of the Ceremonies) produced a contrivance to see whether a mechanical muscle could be made by art, performing without labour the same office which a natural muscle did. Robert Boyle presented his "Sceptical Chymist" in 1679, which a committee were to peruse to see what could be learnt

from it. Moray presented the stones taken out of the Lord Balcarres' heart, in a silver box, together with a written account of the dissection of his body, attested by a physician. Only, in case the deceased lord's mother should claim it, it was not to be denied her.

Much time was taken up in discussing transfusion questions and arranging experiments. But what are we to think of Dr. Clarke's proposition that a man hanged might be begged of the King, to try to revive him, and that, in case he were revived, he might have his life granted him? In 1681 (Wren in the chair) it is recorded that Mr. Flamstead having cavilled against the method shown by Mr Hooke of describing a parabola, the Society desired it again. Upon which the president declared it was true and certain. Honour to whom honour is due. Sir Robert Moray had presented from Prince Rupert an instrument of his Highness's invention for "casting any platform into perspective." It was ordered that the president (and others) wait upon the prince, return him the humble thanks of the Society, and show him an instrument of Dr. Wren's invention for casting any natural object into perspective. In 1666, Mr. Peter Lely was moved to communicate curiosities in the art of painting. Evelyn, Hooke (and others) were to meet and consider particulars. Report was made of willingness to serve the Society. We have, however, been unable to glean any issue.

His Majesty King Charles II. came upon the scene with a fanfare, thanks to the interest of Sir Robert Moray, the courtier, and the gentle scholarly Evelyn. It was long hoped and expected that his Majesty, as founder, would attend one of the meetings. However, he never came. "Early Science" speaks of the appointment of a committee to consider the manner of the King's reception and the conduct of chosen experiments, one being the contriving of optical pictures.

There must, however, have been considerable personal intercourse with his Majesty. Christopher Wren was charged by express command to make a great globe of the moon. On January 23, 1667/8, the operator was ordered to hasten the making of a thermometer for the use of the Queen. In the following year the president took notice that an experiment shown to the Society by Robert Boyle did not succeed at first at Whitehall, but at last it succeeded very well, and in his Majesty's presence. "Early Science" has omitted a pathetic story. In 1663, in a discussion of a new way of hatching pigeons, Sir Robert Moray was able to relate that the King, *when very young*, meeting with a blackbird's nest, and finding but one young one in it, carried it home in the nest, and put it to a thrush in a cage, who fed the blackbird as carefully as if it had been her own, but with this difference, that whereas other birds fed their young ones just before they feed themselves, the thrush fed herself before the blackbird.

The Society enjoyed the supreme advantage at its foundation, and for fourteen years, of the secretaryship of Henry Oldenburg. This accomplished man, a Latin scholar and able linguist, laboured indefatigably and exclusively in its interests with a true spirit of service. With extraordinary zeal he maintained a voluminous correspondence with philosophers abroad, and hence linked up and broadened the philosophical learning of his time. He would seem to have done his best to avoid the credulous and trivial.

Foreign visitors came ever and anon, providing a useful interchange of views. The Danish Ambassador was brought by Evelyn on February 13, 1660/1, and was given a sight of Mr. Boyle's air-pump. The Genoese Ambassador came on January 29, 1661/2. Leibnitz was present at the meeting of January 22, 1672/3 (Hooke, Boyle, and Oldenburg were there). The following year he was elected into the Society. Huygens was elected on June 22, 1663, at the same time as Sorbière (who afterwards narrowly escaped being struck off the roll). The Moroccan Ambassador was a visitor in 1682 and inscribed his name in the charter-book in Arabic. Later, he was responsible for an account of a person who was always dumb, except at noon! The Florentine envoy came in 1685 and was entertained by Papin.

The president and officers were at one period gravely concerned over the arrears of subscriptions, a very large total liability having arisen by degrees. Various fellows undertook to approach the forgetful ones. Not much advance was made in the case of Edmund Waller, the poet, though certainly his interest in the organisation was no more than dilettante. It was mentioned that he had put it off with an expression of merriment; that he thought it best to forget and forgive one another for what was past, and to begin on a new score. This was very disturbing to Oldenburg. In point of fact, Waller never did pay.

Pepys was elected February 15, 1664/5, and admitted the same day. On January 14, 1674/5, at a meeting at which Mr. Pepys and the Earl of Aylesbury were present, each took a day when they would provide a lecture for the Society. The latter excused himself, subsequently paying a fine of forty shillings. Although not recorded, it would appear that Pepys failed to keep his promise. We have found no reference to this lapse in the well-known Diary.

Limitations of space forbid further review; and so we take leave of these "early philosophers," grateful for efforts which shaped into actualities, and for their rich legacy of an essentially English foundation.

T. E. JAMES.

The Physiology of Colour-Change.

The Pigmentary Effector System: a Review of the Physiology of Colour Response. By Dr. Lancelot T. Hogben. (Biological Monographs and Manuals.) Pp. xi+152. (Edinburgh and London: Oliver and Boyd, 1924.) 10*s.* 6*d.* net.

AMONG the many unsolved problems of animal life, the significance of pigmentary colour and of rapid colour-change is one of the most elusive and attractive. Unlike the case of chlorophyll, the pigments of animals have no direct physiological value so far as really critical evidence goes at present. The colouring matters of birds' eggs, for example, the variable colouring of the egg of the guillemot, herring-gull, or cuckoo, has not yet been shown to possess the slightest relation to the welfare of the chick; nor has the (genuine) coloration or lack of colour in the skin or deeper tissues been proved conclusively to play a definite part in the welfare of the animal body. On the other hand, adaptational and survival value has been freely admitted, until recently, to account for the complex and exquisitely balanced correlation between coloration, habit, and environment in a large number of instances, of which insects and fishes offer the most notable examples. The difficulty that has made biologists sceptical of arguments that are used to prove protective, warning, and epigamic significance in animal colouring, lies in the absence of objective standards of excellence. How much does it benefit a flat-fish to fit so exactly into its niche and to stay there? How much does the note of warning avail? What was the value of the rough study in pigment before the painted animal canvas became amenable to the criticism of life? Are pigments or structural colours anything more than indices of chemical and physical structure, and is their biological value real or apparent only?

To these questions Dr. Hogben's book offers no direct answer, and much more analytical work has to be done before we can put really intelligent questions about animal coloration to the test of experiment and observation. What this excellent book does, is to analyse critically all that is accurately known about those quick changes of colour for which the chameleon has gained a wholly undeserved notoriety and in which it is excelled both in rapidity and range of repertoire by many fish, frogs, prawns, and cuttle-fish. Dr. Hogben's book is a critical review of the factors governing colour-change in vertebrates and Crustacea, and his special qualifications for this work lie not only in his own original contributions to experimental chromatology, but also in the judicial way in which he deals with the evidence and shows in each case what the problems are that now await solution. Such a survey will only require to be known to be at once appreciated by zoologists and physiologists as an indication of the new *rapprochement* that is taking place between these two bodies of workers, and that constitutes a reversion to that earlier practice when, as the editors of this series remark in their preface, "animal physiology was not yet divorced from morphology."

Colour-change is a response by the pigment cells of the skin to change in the external or internal environment. It takes the form of radiation of pigment, or of pigmented protoplasm, from the body of the cell into its spreading branches, an injection as it were of granules into a pre-existing dendritic pathway. When this occurs the general effect is darkening of tone. The frog, for example previously yellow, now becomes dark green or almost black Again, the change may be one of pallor occasioned by the inflow of pigment from the branches into the central cell-body leaving, therefore, relatively large tracts of skin uncoloured or exposed so that the less mobile but lighter coloured groundwork—the body of the colour-scheme—becomes thereby visible. Such changes of coloration may be general or local. They may be slow or almost instantaneous. They may occasion a passing flush or a momentary pallor, or they may persist so long as the animal that exhibits them remains in a chosen habitat. They may come on at night and again at daybreak, and the rhythm of nocturnal and diurnal colour contrast may persist even when day is turned into night or night into day. As Lord Lister said in his classical paper on "The Pigmentary System of the Frog" (1858), the pigment cells "form a tissue with entirely new functions which, though apparently allied to the most recondite phenomena, yet produce very obvious effects."

Dr. Hogben's book is a commentary on these prophetic words. The pigmentary tissue gives evidence, accumulated now from the side of endocrinology as well as from those of neurology, of ecology, and of toxicology, of being "allied to the most recondite phenomena." Lister advocated the colour-changes and pigment-cells in the frog for use as "indicators" of the effects of poisonous substances on the animal organism. It has taken exactly sixty years for his suggestion to be carried into effect. The chromatophores of the frog and of the fish are now the most delicate tests of reaction to physiological and pharmacological stimulation; and as there exists a close if not an exact correlation between the action of drugs on a given tissue and those of the sympathetic and parasympathetic (or in the modern sense the "autonomic") nervous systems, change of colour—the radiation and

retraction of pigment in the cell—acquires merit not only in itself as a biological factor, but also as a signpost in the maze of hormonic and autonomic changes that take place in the body.

As an example of this modern development of chromatology we may take the case of an American fish Fundulus Spaeth has shown that the tissue overlying a few detached scales and containing the mobile chromatophores can be studied in a living state under the microscope and the reactions of these pigment cells to various agencies can be recorded. Normal saline promotes expansion of the pigment into a dendritic form, whilst potassium and alkaline salts generally cause immediate retraction. These opposing effects can be balanced by using three reagents in suitable combination (NaCl 6 vol. + KCl 1 vol. + $CaCl_2$ 0·35 vol., N/10 in each case). Equilibrium having thus been attained, it is now possible to determine the effect of any given pharmacological reagent quantitatively by measuring the time taken by, and the extent of, pigmentary response. In this way, Spaeth has accomplished a pharmacological assay, and in the course of it he has discovered the remarkable effect of barium chloride (N/10). When this is applied to the pigmented tissue, the granules at once flow centrally and remain retracted for half an hour. Then the chromatophores at the edge of the scales suddenly radiate their pigment but almost immediately retract it again. There then follows a "Piccadilly effect." The pulsations begun by the cells at the edge of the scale, spread centripetally from cell to cell, increasing in amplitude of vibration as time goes on. Eventually the whole group of pigment-cells associated with each scale pulsates for several hours between the extremes of contraction and expansion.

The importance of these observations and of others on the effect of ergotoxine and adrenalin lies in the fact that the pigment-cell of the fish has one sympathetic nerve-ending and probably one only. Moreover, the pigment-cell, if not a modified smooth muscle-fibre, is a member of a closely allied "effector system," and the evidence it supplies as to the action of drugs and of hormones (such as ergotoxine and adrenalin respectively) throws light upon the action of these substances in the roots of the mammalian uterus. It is indeed an unexpected development of biological research to find the study of pigment a help to the gynæcologist.

The general conclusions that Dr. Hogben draws from his study of the factors governing colour-response in the lower vertebrates and Crustacea are based on a critical examination of the evidence. In the Amphibia, he concludes that the pituitary (posterior lobe) is the source of the effective stimulating substance that, in correlation with the action of natural stimuli, regulates colour-response; and that nervous control of the chromatophores, even if it exists, plays a very subordinate part. In fishes the weight of regulation lies, on the contrary, with the nervous system and owes little to hormonic influence. In reptiles, pallor is the result of adrenalin affecting the chromatophores, but the flushing of the skin with colour is not clearly understood. Finally, the factors for colour-change in Crustacea are ably dissociated and set out on the basis of Gamble and Keeble's work on Hippolyte, and the work ends with a short appendix on the chromatophores of cephalopods.

The volume, from its style, critical treatment, and breadth of view, should enhance the author's reputation and give encouragement to the editors and publishers to pursue the excellent object they have in view—the production of monographs on experimental biology by those who have something to say and are able to say it.

The Recognition of Minerals by their Optical Characters.

(1) (*a*) *Les méthodes de Fédorof et leurs applications à la détermination des plagioclases.* Bull. Suisse de Minéralogie et Pétrographie, tome iii. fasc. 1-2, par L. Duparc et M Reinhard, 1923. (*b*) *La détermination des plagioclases dans les coupes minces*, Mémoires de la Société de Physique et d'Histoire naturelle de Genève, vol. 40, fasc. 1, par L. Duparc et M. Reinhard, 1924.

(2) *Mikroskopische Physiographie der petrographisch-wichtigen Mineralien.* Begründet von H. Rosenbusch. Band 1. Erste Hälfte: Untersuchungsmethoden. Fünfte, völlig umgestaltete Auflage, von Prof. Dr. E. A. Wülfing. Zweite Lieferung. Pp. iv + 253-532. (Stuttgart: E. Schweizerbart'sche Verlagsbuchhandlung G.m.b.H., 1924.) n.p.

THE employment of crystal optics in the determination of minerals is a very special branch of applied physics which has been industriously pursued in recent years, but it is the task of distinguishing between the different plagioclases that has called for the greatest refinements. These important constituents of igneous rocks present the closest resemblance to one another, but vary greatly in composition, forming a continuous series from albite, soda plagioclase rich in silica, $Na_2OAl_2O6SiO_2$, to anorthite, lime plagioclase, $CaOAl_2O_3.2SiO_2$, which contains much less. They differ, however, in the orientation of their axes and planes of optical symmetry relatively to their crystal structures, and in other optical characters. The foundations of these investigations were laid by Schuster,

in Germany, and Michel Lévy in France, but it is to the great Russian crystallographer Fedorov and his pupil Nikitin that we owe the latest and most far reaching developments, and they have now been rendered generally available by Duparc and Reinhard in Switzerland, and by Wülfing in Germany, in the works before us

For this purpose a microscope with a theodolite stage is employed, that is to say, one in which a thin rock slice, containing a section of plagioclase, can be rotated successively on at least three different axes at right angles to one another, so that, with the help of glass hemispheres to prevent refraction, it may be examined from any direction As the amounts of these rotations are recorded on graduated circles or arcs the resulting position is exactly determined

It is well known that plagioclase almost invariably occurs in twin crystals consisting of at least two differently orientated component parts which are related by the fact that a rotation of one of them through an angle of 180° about a definite direction, the twin axis will bring it into parallelism with the other There are a number of different kinds of twins of plagioclase, each with its characteristic twin axis but it is by no means always easy to say which is present

By a series of manipulations of the theodolite stage the three axes of optical symmetry, the so-called 'axes of elasticity,' with the refractive indices α β, γ, of one of the components of the twin crystal are brought in turn into a position parallel to the external horizontal axis of rotation of the theodolite stage, and their positions relatively to the normal to the thin rock section are read off on the graduated circles or arcs These axes of optical symmetry are represented by three points on a stereographic projection in which the normal to the rock slice is the centre of projection

The same procedure is followed with regard to the other component of the twin, and the three corresponding points are inserted in like manner on the same projection. If now great circles are drawn through each of the pairs of points representing corresponding axes of optical symmetry, the three great circles will meet in two opposite points, only one of which will as a rule be represented on the projection. Such a point (or points) will represent the twin axis, and its angular distance from the axes of optical symmetry is then measured, but so that if it exceeds a right angle the supplement is taken.

Recourse is now had to another stereographic projection. This is on tracing paper, and in it the point representing the intermediate axis of optical symmetry with refractive index β occupies the centre, and the other two with refractive indices γ and α are on the circumference at a distance of 90° from one another The position of the twin axis can now be indicated, because its angular distances from the three axes of optical symmetry are known They are of course the same for both components of the twin The new projection is next compared with a standard projection on the same principle which will be found in the works referred to above It shows the positions relatively to the axes of optical symmetry of the crystal directions of the plagioclase especially the twin axes Instead of the crystal directions being considered as fixed and the optical directions as varying with the composition of the plagioclase exactly the opposite convention is adopted, the axes of optical symmetry being regarded as fixed and the crystal directions as varying with the composition The position of the point representing the twin axis of a twin according to any particular twinning law will therefore vary with the composition of the plagioclase, and the points representing such a twin axis in all the different plagioclases will form a curved line, one end of which will correspond to albite and the other to anorthite The intermediate points corresponding to plagioclases with 10 20 30, etc of anorthite are figured accordingly The standard projection shows a number of such lines, each corresponding to a particular kind of twinning

By placing the tracing paper with the projection of the twin axis under investigation over the standard projection so that the corresponding axes of optical symmetry coincide and noticing (1) on what line in the standard projection the twin axis in question falls, and (2) on what part of that line, it is known at once (1) what is the nature of the twinning, and (2) what is the proportion of anorthite present in the plagioclase

The optical axial angle is also obtained in the course of the investigation

In the publications by Duparc and Reinhard this method is explained with a wealth of diagrams and examples, and the older methods are also fully described and illustrated in greater detail than by previous authors A full and clearly illustrated account of the Fedorov method is also given in the Stuttgart publication This forms, however, only a small section of the new edition by Wülfing of the great classical work by Rosenbusch on microscopical petrography It contains in addition a thorough exposition of the general theory of the microscope, of which petrologists, as a whole, know far too little Considerable space is devoted to the description of different types of petrological microscopes and their accessories and their use. The high standard of previous editions is maintained and even surpassed, for all the latest advances will be found in its pages JOHN W EVANS

The British Portland Cement Industry.

A Hundred Years of Portland Cement, 1824–1924. By A. C. Davis. Pp. xxii + 282. (London: Concrete Publications, Ltd., 1924.) Cloth, 21*s*.; leather, 25*s*.

SOME books are of transient value and others increase in value as time progresses. This work undoubtedly belongs to the latter class. The author's intimate knowledge of the cement industry, its complex business ramifications, and changing methods of manufacture, has enabled him to produce a book which must be regarded as authoritative over the period of which it treats, so far as the British industry is concerned. No attempt is made to follow the development of the industry in other lands, beyond what is essential for understanding it in our own.

After a brief survey of the knowledge of the ancients regarding limes and cements, and a critical examination of John Smeaton's work in 1756, the tangle of men and names associated with the beginning of the industry in different parts of England is gone into in considerable detail, this section of the work being illustrated by excellent actual photographs of historical value. The cement industry is now so rapidly changing that all these old landmarks of progress may in the near future be swept away, and the men who took an active part in its development and remember the conditions which prevailed in the industry even a few decades ago are now fast disappearing. The work, therefore, is valuable in that it gives an accurate account of the industrial conditions and influences which prevailed in the industry, following the gradual change until we reach modern conditions, when great accumulations of capital, expensive machinery, and accurate scientific control by routine chemists and scientific engineers are essential for successful manufacture.

What must strike the reader of this book is the unattractive personality and lack of education of the pioneers of the industry. The work of Joseph Aspin, and especially of his son William, is gone into in some detail. Did any of the Aspins really know how to produce the substance known now as portland cement, a substance which is produced by increasing the heat in the kilns sufficiently to cause the intimate union of the components accompanied by semi-fusion or "sintering"? The author decides that they did not. The original patent of Joseph Aspin is obviously deficient, and it has been suggested that the inventor suppressed vital information in order to mislead competitors. Mr. Davis decides that the Aspins never made what was now known as portland cement, although Joseph Aspin introduced what has proved the extremely successful trade name of "Portland Cement," and in this showed considerable ability. The fact of the matter is that both the Aspins were ignorant but gifted men, deficient in education and devoid of all scientific knowledge.

Joseph Aspin, the father, was a bricklayer by trade, a Yorkshireman, who seems to have distrusted his fellow-manufacturers to a considerable extent, as he surrounded his factory with walls 20 ft. high and carried on the manufacture as a sort of mystery. His son William continued this tradition, mystifying his workmen by sprinkling various secret chemicals from a tray on to the contents of the kilns in front of his workmen, with the result that he not only repeatedly succeeded in raising capital after each failure, but also succeeded in baffling inquiries right to the end. After repeated failures he died in Germany as the result of a fall while in an intoxicated condition, his last partner having got rid of him by a cash payment of 2500 marks.

This origin is no doubt the cause of the suspicious attitude towards all people who claim superior knowledge, which even to-day prevails to some extent in the industry, chemists and scientific workers generally being regarded with marked disfavour.

A man of greater ability than either of the Aspins was I. C. Johnson, who spent some time in spying around Aspin's works with the view of discovering his "secrets." He apparently quite met his match in the Yorkshireman, because the sample of material that Aspin supplied him with turned out to consist largely of calcium phosphate, which led Johnson to collect all the bones in his neighbourhood and burn them so as to create a mighty stench. Needless to say, he did not make portland cement with this material, but promptly silenced any criticism by blaming the analyst for making an incorrect analysis.

Johnson himself seems to have possessed only elementary scientific knowledge, but his ability was undoubted, and by means of numerous experiments made on the "trial and error" principle, he undoubtedly succeeded in making portland cement as we know it to-day. He also introduced the chamber kiln into England, and the enormous British industry which developed was largely due to this invention.

The cement industry seems to have been carried on in the crudest way, without scientific control of any sort, and a graphic description of the way a cement works was run in 1886, on p. 211, brings this aspect home to the reader, especially when a chemist will remember that at this time the German chemical firms for years past had been not only employing routine chemists to control output, but also, so far back as 1883, the Badische Anilin und Soda Fabrik was actually employing a director of scientific research at a salary of 5000*l*. per annum.

It was the shock of foreign competition which led to

improved methods of manufacture. Routine chemists were engaged to control output and material, the rotary kiln was reintroduced from the United States (after its initial invention and failure in Great Britain), and, generally, the industry took on its modern form The author claims, and the reviewer thinks correctly, that at the present time the British cement industry is conducted with practical skill and accurate scientific control which equals, if it does not exceed, that exercised by any other country, but that great improvements are still possible in manufacture.

The author furnishes an interesting chapter on the progress of scientific research in the industry. To sum up, the work is a valuable one, and gives an exact and very accurate picture of the cement industry as it exists to-day, and illustrates clearly the successive changes introduced into the industry in the successive decades The work will enhance the author's reputation as one of our leading authorities on cement.

GEOFFREY MARTIN.

Prehistoric Man.

Fossil Man in Spain. By Prof. Hugo Obermaier. (Published for the Hispanic Society of America.) Pp. xxviii+495+23 plates (New Haven: Yale University Press; London. Oxford University Press, 1924.) 23s. net.

DR. HUGO OBERMAIER was born in Bavaria, worked under Hoernes at Vienna; studied glacial geology throughout the Alps with Penck; excavated for the Prince of Monaco the largest and most important prehistoric dig at present known at Castillo (Cantabria); was professor, until the War broke out, at the Institute of Human Palæontology founded by the same Prince at Paris; and now is professor of prehistoric archæology at the University of Madrid. With such a record we may well expect a fine work and Dr. Obermaier has not disappointed us. To the German thoroughness and power of taking pains in details born in him, there has been added, from long association with the French, the Latin clarity of thought and power of intuition. Madrid has done well to envisage all this and come forward with a professorial chair when war difficulties approached. It is not too much to say that Dr. Obermaier is one of the two most learned prehistorians now alive.

It was in 1912 that his book "Der Mensch der Vorzeit" appeared, and this was followed in 1916 by "El Hombre Fosil," with a translation of which from the Spanish into English, accomplished thanks to the enterprise of the Hispanic Society of America, we are now concerned. It is a monumental work that will long retain a foremost place in the prehistorian's library, though no specialist has heretofore been able to do without the original Spanish edition. A few changes have been introduced in the new version and the book has to a large extent been brought up-to-date. This has been facilitated by the fact that, owing to innumerable delays in the United States, the production of the English edition is coinciding in time with the preparation of a second revised edition in Spanish, and it has been found possible to incorporate some of the new matter in the present volume. There are also alterations and additions in the plates, which are many and excellent. In the reviewer's opinion the English title is somewhat misleading, as the work is really of a general character, though stress is laid in the illustrations and text on the Iberian peninsula—"Fossil Man, with special reference to Spain" would really be a more accurate description.

The book opens with an account of Tertiary times and the problems of Tertiary man, followed by an exceedingly able summary of the existing knowledge of the Glacial epoch with lists of the plants and animals found.[1] Next comes a description of the various Palæolithic industries, a special chapter being devoted to the Iberian peninsula during these times It is pleasant to see here the introduction of a new plate figuring a general view of the cave of Castillo, where the reviewer had the privilege of assisting at the digging of this really wonderful site under Dr Obermaier's direction. Palæolithic art and the problems of chronology are then discussed, and the volume concludes with two chapters on fossil man and the transition from Palæolithic to Neolithic times successively. Not the least valuable part of the work is the group of appendices, notes and bibliography, which, in the English edition, are separated from their respective chapters and placed together at the end. Some minor changes in arrangement have been introduced which seem to be on the whole an improvement. Thus the order of the table on page 64, giving the archæological sequence of the various industries in the Somme valley, has been reversed from that of the Spanish edition, the latest deposits being placed at the top instead of at the bottom of the list. There are also one or two minor misprints of little importance, for example in the initials of at least one author quoted.

Of course, in any work of this nature there must be, besides basal and incontrovertible facts, theories which are not necessarily accepted by every one. For example, Dr. Obermaier's suggestion as to the significance of the Azilian painted pebbles, that the markings really represent conventionalised human figures, has always seemed to the reviewer difficult of credence; and his

[1] A translation of the whole of this chapter from the Spanish edition is given in the appendix—the main text contains a rewritten version not quite so overloaded with technicalities and mere lists.

comparison of them with the undoubted conventionalised figures of the Spanish Third Group paintings seems open to the objection that there is by no means an exact similarity, and, moreover, that the latter are very possibly of a much later date. However, these are points that further finds will no doubt elucidate.

It only remains once more to congratulate Dr. Obermaier on his book, and the Hispanic Society of America on having been the instrument of introducing it more fully to English readers. M. C. B.

Fluid Velocity and Pressure.

The Measurement of Fluid Velocity and Pressure. By J. R. Pannell Edited by R. A. Frazer. Pp. vii+135. (London: E. Arnold and Co, 1924.) 10*s* 6*d*. net.

TO a large extent this book is a product of the advent of aeronautics, and its preparation would not have been possible fifteen years ago. The author passed through the period during which no accurate means existed of measuring the velocity of fluids, and was intimately associated with the history of the needs of such methods as he describes. At the present moment, the calibration of anemometers depends on a solitary series of absolute measurements at the National Physical Laboratory, part of which was conducted by the author himself. The work of Stanton on wind pressure in 1903 was the first contribution to the production of the tube anemometer illustrated on p. 13; its establishment as a satisfactory standard followed the formation of an Aeronautics Department, and the development then reached the stage at which a skilled workman can reproduce the instrument so accurately as to give speed within one per cent. without special test.

Many other anemometers, including those established in aeronautical practice, are described together with manometers and balances for the measurement of fluid pressures. In the description of one of the manometers —p. 92—the short statement occurs that "the horizontal tubes are filled with a solution of distilled water and common salt of density 1·07 . . ." and no reference is made to the lengthy inquiry made by the author before this solution was decided on. In the early days of the use of tilting manometers of the Chattock type, distilled water was tried, with the result that renewal was necessary after each fortnight or three weeks. The glass work had then to be thoroughly cleaned. As a result of Pannell's efforts the period between cleansings was raised to a year or more and the operation of cleaning greatly facilitated. In this and in much of the material in the book under review there is just that precision of detail which is helpful to newcomers and will enable them to get to work quickly and safely.

Pannell lost his life when the airship R38 failed, whilst applying his knowledge of instruments to research, and together with his colleagues the author has left a record of which one is proud and of which this book is one item. The volume can be confidently recommended as an excellent statement of available methods of measurements in the motions of fluids, whether the application be in aeronautics, hydraulics, ventilation, or any other of the branches of engineering.

L. BAIRSTOW.

Our Bookshelf.

Soil Management. By Prof. Firman E. Bear (Wiley Agricultural Series.) Pp vi+268. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1924.) 10*s*. net.

THE work under notice is a text-book dealing with the application of scientific facts and principles to the practical management of the soil, and is written for the use of students in agricultural colleges who have already taken courses in chemistry, botany, geology, and physics. The requirements of crops and the properties of soils are discussed in the first ten chapters, which are followed by four chapters on the utilisation of the resources of the soil by cultivation operations, crop rotations, etc. The remainder of the book is concerned chiefly with the economic use of fertilisers and of lime. The nitrogen problem is treated with the thoroughness that would be expected from Prof. Bear, who has devoted much time to this question. It is a very common practice in the United States to purchase only phosphatic fertilisers and to depend on the air for nitrogen; on soils which have been cultivated for many years, such a system necessitates the well-managed introduction into the rotation of frequent leguminous crops for green-manuring, and the author is rightly insistent that every effort should be made to utilise such natural nitrogen-fixing agencies to the fullest possible extent for the maintenance of soil fertility.

The illustrative data are taken mainly from American sources, but the application is by no means confined to American conditions. It may, however, be questioned whether the book is not on the whole too advanced for students who "have little or no need for the course except as it may be useful to them in practice or in understanding practice." Certainly the average British student of this type will find it rather stiff reading; but his American cousin is perhaps different. C. T. G.

The Bombyliidæ of the Ethiopian Region: Based on Material in the British Museum (Natural History). By Mario Bezzi. Pp. viii+390: 46 text-figs. (London: British Museum (Natural History), 1924.) 32*s*. 6*d*.

THE Bombyliidæ are a large and highly interesting family of Diptera, and the present monograph forms an important contribution to our knowledge of these insects. In placing the preparation of the volume in the hands of Prof. Bezzi, a wise choice has been exercised.

since that author is well known as one of the leading dipterists of to-day. The book is based upon material submitted to him by the British Museum and the Imperial Bureau of Entomology as well as from the Museums in Cape Town, Buda-Pest, and Genoa, and also from Messrs. Alluaud and Jeannel in Paris. This wealth of specimens, together with those in the author's own collection, has made it possible to produce a monograph of great value. In addition to diagnostic keys and descriptions, all available biological data, however scanty, is included under each species together with notes on the known life-histories. It is hoped that, with the aid to identification thus provided, African entomologists will be stimulated to study the remarkable metamorphoses of these insects Their larvæ are all parasites and have a wide range of hosts. The unexpected discovery of *Thridanthraxabruptus* parasitising the puparia of tsetse-flies is but a bare indication of what awaits investigation in the Ethiopian region. The book is admirably printed and illustrated, while the revision of the English manuscript by Major Austen has ensured this arduous task being carried out capably.

Distillation du bois. Par Prof. G. Dupont. (Encyclopédie Léauté, 2e série.) Pp. xv+284. (Paris: Gauthier-Villars et Cie; Masson et Cie, 1924.) 25 francs.

THE general treatment in this work is on somewhat similar lines to that followed in recent British and American text-books on the subject. Special attention is given to the distillation of resinous woods, and an interesting account of wood distillation plants is included, the text being made clear with numerous diagrams. There is a certain lack of proportion in the presentation of facts. Nearly one-third of the book is given over to an account, such as is available in numerous organic text-books, of the elementary chemistry of acetic acid and methyl alcohol, and of simple derivatives of these, yet the study of the gaseous products from the thermal decomposition of wood is intentionally neglected. Again, the analytical section is considerably restricted. The space occupied by this important subject is only half that given to the preparation and properties of formaldehyde, and it is doubtful if the meagre information therein contained will be of much real value to the analyst.

The monograph cannot be regarded as a handbook for the specialist. It is rather a general account of certain aspects of wood distillation presented in a form which will be attractive to the general reader and science student. J. REILLY.

Aristotelian Society. Supplementary Vol. 4. *Concepts of Continuity: the Papers and Symposia for discussion at the XIVth Joint Session of the Aristotelian Society and the Mind Association, at University College, Reading, July 11-14, 1924.* Pp. vi+240. (London: Williams and Norgate, 1924.) 15s. net.

THE papers read at the summer meeting of the Aristotelian Society and the Mind Association, though inspired with a distinctively philosophical motive, are of more than usual scientific interest All in some form deal with the subject which gives the title to the volume, the concept of continuity.

Prof. Chevalier's article "Le Continu et le Discontinu" is designed to prove that though the problem of continuity is fundamental in mathematics and physics, it can be resolved only by philosophical arguments.

Three of the five symposia deal with scientific problems. One on the quantum theory discusses how far it modifies or can be made to accord with the definitions of continuity accepted in mathematics, physics, and psychology. The papers are by Dr Nicholson, Mrs. Wrinch-Nicholson, Prof. Lindemann, and Prof Wildon Carr. A second deals with the biological problem of the transmission of mental characters This is discussed by Profs. Johnstone, Dendy, MacBride, and Lloyd Morgan. A third deals with the implications of the term "law" in psychology. The papers are by Mr. Wolters, Dr. M'Intyre, and Dr. Levine.

Chemical Thermodynamics: an Introduction to General Thermodynamics and its Applications to Chemistry. By Prof. J. R. Partington. Pp. vii+275 (London. Constable and Co., Ltd., 1924.) 10s. 6d. net.

A NEW edition of Prof. Partington's "Text-book of Thermodynamics with special reference to Chemistry" (1913) has been desired for some time, and those who are familiar with that work will welcome it in its new form under the title "Chemical Thermodynamics" The treatment has been simplified as well as brought up-to-date Any one who is familiar with the large number of relevant papers published during the past decade will marvel at the skill with which the material has been incorporated. The author has made a special feature of the inclusion of much recent work published in American journals. "The accurate experiments, and the ingenious and original treatment, of the American workers on this subject will make all admit gratefully the debt which students in other countries owe to them." A point which teachers will appreciate is that the equations have been stated, so far as possible, in a form capable of direct numerical application, and many examples, with answers, have been provided. It is a convenience to have the numbers of the paragraphs printed on the inside edges at the tops of the pages. The book will prove indispensable to students of chemistry and physics alike.

Spectroscopy. By Prof. E. C. C. Baly. (Text-books of Physical Chemistry.) In 2 vols. Third edition. Vol. 1. Pp. xi+298. (London: Longmans, Green and Co., 1924.) 14s. net.

THE new edition of Prof. Baly's "Spectroscopy" is modelled closely on the original plan. It has, however, been reset in a new *format* with a larger page, so that the number of pages in the first volume of the new edition is about 10 per cent. less than in the corresponding half of the preceding edition. Since the earlier portions of the book are concerned mainly with prism and grating spectroscopes, they have not needed any drastic emendation as a result of the recent developments in the theory of spectroscopy; but attention may be directed to a useful table of standard wave-lengths, covering three pages of the new edition, and to the account that is given of recent work by McLennan and by Millikan on the extreme ultra-violet region of the spectrum.

Letters to the Editor.

Limbs and Pigment-Cells.

I NOTICE in a review of Franz's "Geschichte der Organismen" which appeared in NATURE of December 20 a reference to the interesting evolutionary problem of the origin of the limbs of vertebrates. I have no intention of essaying the futile task of endeavouring to influence those whose minds are already made up regarding this problem, but I should like to direct the attention of others to the point that new facts having important bearings upon the problem have come to light in the investigation of the development of these relatively archaic types of vertebrate, Lepidosiren, Protopterus, and Polypterus. A short summary of these facts, and of the conclusions they suggest, will be found in my volume on vertebrate embryology, and the perusal of this summary will, I think, suffice to indicate the grounds for my belief that the older hypotheses referred to by the reviewer will, as knowledge of the relevant facts becomes diffused, be replaced as working hypotheses by the newer view that the limb of the vertebrate has evolved out of a projection from the body-wall which was primitively respiratory in function.

I take this opportunity of directing attention to another statement in recent literature which is liable to cause misunderstanding. It occurs in a book by Dr. L. T. Hogben entitled "The Pigmentary Effector System," where he refers (p. 93) to "Kolliker's work on the South American mud-fish, Lepidosiren." The creature upon which Kolliker worked was of course not the creature known to us to-day as Lepidosiren, not the South American "mud-fish," but the African Protopterus which for a brief period after its discovery was called Lepidosiren. As Dr. Hogben does not refer in his summary of our knowledge regarding the pigment-cells of fishes either to what I have published on the subject, or to what I made known to him by word of mouth, I will state very shortly the attitude that my work upon Lepidosiren caused me to take up, and which I have consistently adopted in teaching for many years. I adhere to the view that the colour change, so beautifully exemplified by the young Lepidosiren—of a deep rich black during the day and practically colourless during the hours of darkness (see *Phil. Trans. Roy. Soc.* B, *192*, *1900*, and *Quart. Journ. Micr. Sci.* 46, 1902), is due to actual change in the form of the black pigment-cells which, under the influence of light, push out their finely branched pigment-laden pseudopodia in a direction parallel to the surface of the body so as to provide a light-proof coat, and, when night falls, draw in their pseudopodia and shrink up to spheres so relatively small as to be without effect upon the general colouring. The considerations which induced this opinion were (1) the appearances presented under the microscope, (2) the fact that the pigment-cells changed their position in the body and therefore necessarily had the power of moving their pseudopodia, and (3) the fact that it was possible by teasing up the night skin to isolate individual chromatophores without their going to pieces as they would be liable to do were peripheral extensions of their body torn through in the operation.

As regards the active functioning of the pigment-cells, there is, I think, a tendency towards over-emphasis of one or other of the factors involved. There is, first of all, the fact that the healthy activity of the chromatophores, as of all other cells in the body, is dependent upon the internal medium of the body being of approximately "normal" composition, and recent work by various investigators, including Hogben, has served to emphasise the special importance of particular components of the internal medium provided by the adrenal or the pituitary organ, slight fluctuations in the proportion of this particular component evoking specific functional responses. There is, secondly, the nervous factor, and there is, thirdly, the direct influence of light.

As regards the latter, I may quote an observation made by me in South America. I happened to be watching a green tree-frog in the sunlight and admiring the extraordinarily perfect agreement between its colour and that of the surrounding leaves. Across its back fell a dark narrow bar of shadow caused by a blade of grass close by. When I caused the tree-frog to change its position it appeared, to my astonishment, to carry the shadow with it, the position where it had been remaining for some little time clearly indicated by a dark band across the green surface. That observation served to impress upon my mind very vividly the fact of response by the skin chromatophores to localised light stimulus, and while such responses may turn out to be complicated reflexes involving the central nervous system, it seems to me simpler, until convincing evidence to the contrary is produced, to regard them as direct cellular reactions to changes in the incidence of light rays.

Muscular Action.

DURING the last few years a considerable number of papers have appeared bearing on this subject. They may be divided roughly into two classes, the first dealing with the fatigue caused by muscular action, together with the nature of the accompanying waste products, the second, with the behaviour of isolated muscles under the action of artificial stimulus.

From a mechanical point of view, a muscle is a single-acting engine which can exert a pull but not a thrust: and with regard to any class of engines, some of the most important questions which can be asked are: What is (1) their efficiency; (2) their weight for unit of power; (3) how does the efficiency vary with the rapidity of the stroke (*i.e.* piston speed); (4) how do these quantities vary with absolute size? The physiologist may further inquire: (5) What is the nature of the nervous stimulus and how does it effect the required longitudinal contraction and lateral dilation of the muscular fibres? Electricity will act as a stimulus, but (6) is it certain that nervous stimulus is of the same nature? (7) Does an excised muscle behave in the same way as the muscle in a living animal?

Striped muscle wherever met with—from mammal to insect—varies very little in appearance or in the cross-section of the individual fibres. (8) Is the contractile force which can be exerted by each fibre the same or nearly the same in all orders?

These questions are not answered by any of the papers to which allusion has been made.

In a letter which appeared in NATURE of April 15, 1920, I said. "When muscular force is exerted, power is expended and fatigue is produced, even when the muscle remains stationary. Again, when no external force opposes the contraction of the muscle, physiological causes set a limit to the speed at which contraction can take place. In both cases the whole power

expended is lost in so far as the production of useful work is concerned." [1] For the maximum nervous stimulus the acceleration is limited by the mass of the muscle itself and of those parts or limbs to which it is attached and which must move with it, and the greatest contractive force will act when the muscle is stationary, the whole of the power again being lost by muscular leakage. Between these limits there must be a "most economical speed," *i.e.* a speed which will develop the greatest useful power.

If it is assumed that the leakage is proportional to the tension of the muscle, and is the same for the same tension whether the muscle is stationary or in motion, and also that all the work done in internal acceleration is lost (assumptions which should be the subject of experiment), the most economical speed is that which makes the losses by leakage and acceleration equal. If the operation of the muscles is periodic and is associated, as for example in walking, with a natural gravitational period, part of the acceleration is done by gravity, and the muscles only supply as much as is required to convert the natural period to the period of the step—that is, to convert a free period T_1 into a forced period T_2.

A simple experiment which will show the difference between the power required to maintain the forced and free motions may be made as follows. Crossing the arms so that the wrists are in the same vertical plane, make each hand describe a circle about the line joining the elbows and note the rate of revolutions which can be sustained. Here there is no external work to be done, and, since the average position of the forearms is horizontal, the natural period is infinite. Various muscles, however, must act periodically to balance the centrifugal force. Next place both wrists in a looped strap which will form a wrapping connexion between the arms. This will not interfere with the orbital motion, but the centrifugal force will be taken wholly by the strap, and the forced period may in consequence be any imposed period.

With this arrangement it will be found on trial that for the same sense of fatigue the rate of revolution is more than double that which could be reached when the hands were free. The only work done when the strap is in use depends on the small tangential force required to overcome the viscous and leakage losses.

If there were any direct method of measuring fatigue, experiment on these lines would afford a quantitative measure of the relation between the power spent in leakage and in acceleration.

As regards the behaviour of isolated muscle, H. S. Gasser and A. V. Hill give an account (Proc. R.S., B, vol. 96, p. 398) of experiments on an excised muscle fixed at one end and at the other attached by a thread to a balanced beam the moment of inertia of which was adjustable. The muscle was stimulated by a brief current from an induction coil, and the movements of the beam were observed and recorded.

It is not stated whether the same muscle was used in all the experiments, but it may be gathered that each specimen, if there were more than one, was used many times.

It can scarcely be imagined that a muscle deprived of blood supply can continue to perform work, unless that work is supplied by the stimulating current, but the amount of the electrical work is not given. If, however, the work done by the muscle is merely the equivalent of that supplied by the coil, it would indicate that nervous and electrical stimulation differed in kind, for nervous stimulation seems to act much as an igniter does on a charge of powder, that is, to call up power inherent in the muscle.

It would be interesting to have these experiments repeated in a somewhat modified form. Instead of acting on a massive beam, let the muscle turn a wheel by a ratchet and pawl against a resistance controlled by a brake (these need not weigh more than two or three grams) and let the stimulus be applied periodically. Let an automatic record be provided for the stroke, the brake force, and the electric energy consumed in stimulation, and let the experiments be continued for considerable periods (minutes or hours if necessary). In this way a comparison could be made between the work supplied and the work performed.

A. MALLOCK

9 Baring Crescent, Exeter,
December 22.

[1] In this letter an analogy was suggested between muscular action and the working of an engine with a leaky cylinder. The supposed action would also be indicated if a cord, loaded with a certain mass, the motion of which was opposed by a viscous force, had one end attached to a wheel and brake, while the other was fitted with a hand-grip, which, when tension was applied, would slip at a speed proportional to the pull. Here the turning of the wheel would be a measure of the useful work done, and the slip, of the muscular leakage. If the applied tension was less than the brake resistance the cord would not move, but work would be done by the slip, and if the tension is greater, the mass will be accelerated until its viscous resistance plus the brake resistance is equal to the pull applied.

Constant Differential Growth-ratios and their Significance.

ON Mr Julian Huxley's very interesting results as to the fiddler-crab (NATURE, December 20, p. 895), I suggested at Cambridge that in his equation $y = bx^{1.61-1.64}$, if we are to rationalise the index, $y = bx^{\frac{1}{2}}$ comes nearer to his results than does $y = bx^{\frac{2}{3}}$, and allows of the conceivable physiological explanation that the ratio of claw-weight to body-weight is the isogonous ratio multiplied by a ratio proportional to a growing area in the body. Thus the weight of the claw might be the isogonous weight multiplied by the ratio of an isogonous surface secreting a male hormone to a surface secreting a female hormone and remaining of constant area. I also pointed out that in the roe of the plaice we have a sexual appendage, shed every year, and every successive year showing an increasing rate between its weight and the weight of the body. The parallel proves so astonishingly close that I ask space to communicate the following two facts.

(*a*) Representing the weight of the ripe roe of a plaice as y and the weight of the gutted body as x, then, in plaice of different weights

$$y = bx^k,$$

as Mr. Huxley discovered for the claw of the fiddler-crab. The ration of ovary-weight to body-weight has no relation to age, but only to body-weight, in this, as in some other respects, the age of a plaice is not measured by years but by the quantity of food which it has succeeded in assimilating.

(*b*) In the above equation, from the small sample of data at my disposal, I make

$$k = 1\cdot58 \pm 0\cdot10$$
$$-\log_{10} b = 2\cdot610 + 3\cdot063(k - 1\cdot58).$$

This preliminary investigation has been on data which Dr. Wallace kindly gave me at Lowestoft in 1906 from his manuscript notes (9 fishes, gutted weight 429 to 1800 grams, age-groups IV. to XIV.) and some published by Fulton (vol. ix. p. 263; 5 fishes, weight 1280 to 2145 grams, age-groups VIII. to XVI.). They are insufficient to determine with certainty whether or not k varies with increasing weight; on the whole the most probable conclusion from the data is that k is constant. Since Dr. Wallace's figures include only two fish more than 1100 grams, and Fulton's smallest fish is 1190 grams, it is impossible to test directly the similarity of the two groups; but taking the centre of gravity of the logarithms for the ovary and body-weights of

the three fishes under 700 grams, the line joining this to the centre of the remaining 11 fishes gives $k = 1{\cdot}610$; while the line joining it to the centre of only the 6 larger Lowestoft fishes gives also $k = 1{\cdot}610$. The figure 1·58 has been adopted as giving for the fourteen fishes the lowest average error, 0·0512, in the resulting deduced $\log y$; but the average error with $k = 1\ 500$ is only 0 0553, and with $k = 1{\cdot}667$ is 0 0536, so that the $\pm 0{\cdot}10$ seems to indicate the probable extent of our knowledge (With $k = 1\ 75$ the average error is 0·0626, and with $k = 1\ 25$ it is 0 0781. It must be remembered that logarithmic plotting imparts an illusory aspect of accuracy; errors of 0·051 and 0·078 in $\log y$ represent errors respectively of 11½ per cent. and 20 per cent. in the weight of the ovary.) Further investigation of the extensive data by now available from the North Sea Investigations seems best left in the hands of those expert in the history of the statistics and in the natural history of the material It would be instructive to know whether the increase in ratio of ovary to body-weight means a disproportionately large number of ova, or an isogonous number of ova of increased size? If an "area" really determine the ratio, does it secrete, in plaice or in crab, a hormone promoting cell-division, or promoting cell-growth?

The most interesting question now is whether the fact that $k = 1{\cdot}6 \pm 0\ 1$ in fiddler-crab's claw and plaice's ovary be a chance coincidence, or whether Mr Huxley's index, as well as his law of growth, be found to hold good in yet other animals?

I would urge that the latter suggestion cannot be negatived except by investigation of organisms living in the water The index of the stag's antler would not necessarily follow the same law, for as a terrestrial animal the stag is under the necessity of a waning annual coefficient of bodily growth, since its size must not exceed the size which its legs are adapted to carry. Plaice add approximately an equal weight every similar year; for though the size of an aquatic animal may be limited by the size of its food or of its enemy, it is not affected by conditions of mechanical support. An average man is 5½ feet high, but there is no average length for a plaice; the plaice which is ten times the age of sexual maturity will be a longer fish when she is eleven times that age.

It seems possible that this necessity for a waning coefficient of growth may be the explanation of our death. Our growth-rate wanes very slowly to the zero point at 27 years old, but it does not stop waning when zero is reached. Except for creatures whose life is ended by the winter or summer, and those that perish with the act of reproduction, I do not remember any evidence of a marine animal dying a natural death, as we use the word of ourselves. It is natural for every fish to have life ended by the fangs or jaws of his fellow-creatures; in the waters, is any other end natural? Did old age and death only become the necessary fate for plants and animals when they left the swamps, claimed the land, and attempted swiftness or tallness in a medium 1/800 of their specific gravity? If this be true, it was for proportionment of weight to transverse section that we were compelled to renounce the gift of eternal growth, and to accept death.

GEO. P. BIDDER.

Cambridge, January 5.

On the Efficiency of the Petersen Grab.

THE Petersen Grab is now being much used in various parts of the world for the purpose of picking up a portion of the sea-bottom—where this is soft enough—along with the animals of all kinds contained in the surface layer of that portion of the sea-bottom. When a sufficiently large number of samples can be taken on a homogeneous stretch of ground the grab-samples are made a means of determining quantitatively the average distribution of the sedentary population of that area.

In the earlier illustrations of the instrument, as used by Petersen, two types are shown. One of these types appears to be in general use to-day, and is regarded by the present writer as inefficient, while the other, which appears to have gone out of use, is more efficient in principle, and by a slight alteration can be made reliable in practice.

During a recent survey of the oyster beds in the Fal Estuary, the present writer employed the Petersen grab, but came to the conclusion that the current form of grab was inefficient for the determination of an oyster population; and further, that on grounds

FIG. 1.—Peterson Grab modified to cut into a rectangular surface of the sea-bottom and to ensure partial protection of the gap present during closure. (From a photo by Mr. A. J. Smith.)

in which the grab cannot dig, and probably also to some extent even on soft grounds in shallow water, the grab will not pick up with certainty the extent of surface of the sea-bottom which it is supposed to do. The grab consists essentially of two very nearly quarter-sectors of a cylinder hinged along the axis of the cylinder. When the instrument is closed it has the form of very nearly half a cylinder. The occluding edges of the sectors are very nearly radii of the cylinder end section, and their peripheral ends are separated by a chord of about 36 cm. in the open condition of the 1/10 sq. metre type, in which the diameter of the imaginary cylinder is about 45 cm. The occluding radii of the sectors of this type are only exposed in about 16 cm. at their peripheral end, as a central small metal cylinder of about 12 cm. in diameter is built into the instrument around the main axis. The instrument is closed by a vertical pull on a chain, which passes over a pulley on the inside of one sector and is attached to the inside of the other (Fig. 1). In use the instrument is allowed to run freely and arrive on the bottom with a bang; the check on arrival being utilised to release the chain used for closing and hauling.

It follows from the construction of the grab that, in the act of closing, the gap in the semicircular ends tends to become higher and reach a maximum height of about 15 cm from the line joining the peripheral ends of the occluding sector radii This gap in the instruments at present in use is unprotected, and since the portion of the sea-bottom taken in the instrument cannot slide freely into the cavities of the sectors due to internal obstructions and friction, the captured soil tends to pile up under the middle of the instrument and opposite the gaping ends Consequently, there is grave danger of a portion of the surface with its contained animals becoming lost by being pushed out of the grab at the final closing strokes. The loss of soil from this cause is no doubt greater on muddy grounds than on sandy ones, but has nevertheless to be reckoned with on all types of grounds

It follows, therefore, that quantitative estimates of animals in the sea-bottom made by using the type of grab described are in all probability too low In using the grab for quantitative estimations of oysters, the loss of a single oyster from approximately one square foot of ground is a very serious error, and the instrument was quickly altered to the type shown in Fig 1 by bolting thin steel plates to the sides of one sector, so that when the grab touched the bottom it actually cut into a rectangular piece of soil This modification is, however, still open to objection where animals living *in* the soil are being sought for, and the type of grab which will pick up a definite portion of the bottom soil with certainty is one the end plates of which form a complete semicircle In such an instrument the end plates would cut into the soil before the sector jaws reach it, and protect the gap during the whole of the closing operation

J H ORTON

Marine Biological Laboratory, Plymouth,

The Nature of the Contractile Vacuole.

FOR some years we have been investigating the cytoplasmic bodies in the protozoa In NATURE of March 10, 1923, we were able to give the first account of the stages undergone by the Golgi bodies in the sporozoon Adelea. A full account of this work has been published in the *Q J M S*, vol 67, Part III, 1923 More recently M Ph Joyet-Lavergne (*Comp rend*, 1924) has described the Golgi bodies in *Aggregata Eberthi*, and *Adelina dimidiata*, confirming our account.

For some time our attention has been given to an examination of the Ciliophora and Rhizopoda, in which we have failed to discover anything which we can satisfactorily homologise with the Golgi apparatus of the metazoon

Now, however, Dimitry Nassonov, in the *Archiv f mikr Anat u Entwick*, Oct. 1924, publishes a large paper in which he seeks to homologise the contractile vacuole of the protozoon with the Golgi apparatus of the metazoon.

Nassonov, by means of osmic acid technique, has succeeded, as we have done in our material, in blackening the cortex of the contractile vacuole and the canals leading to it. He claims that this osmiophile membrane has the property of secreting an osmotically active substance into the lumen of the contractile vacuole, and also itself has the distinctive character of a semipermeable membrane

Furthermore, Nassonov gives several reasons for homologising the Golgi apparatus of the metazoa with the contractile vacuole cortex of the protozoa — first, both organellæ are not visible *in vivo*, second, their morphology is similar, both being bladders with an osmiophile wall, third, the sponge (the metazoon nearest to the colonial protist) has a Golgi apparatus which looks like a contractile vacuole, and finally, the Golgi apparatus of the metazoan cell also has the power of secreting various substances

In the first place, Nassonov has shown that the cortex of the contractile vacuole has the power of reducing, and of becoming blackened by, osmium tetroxide We agree fully, having succeeded ourselves in blackening this cortex in a number of ciliates We are also not unprepared to accept some of his interpretations as to the function of this lipoid membrane

When, however, we come to the homology of the metazoan Golgi apparatus and the protozoan contractile vacuole, we feel, at present, that there may be some grounds for doubt The Golgi bodies in embryonic or undifferentiated metazoan cells are almost invariably associated with a centrosphere and centrosome In the ciliates no relation between the contractile vacuole and any body similar to a centrosome can be demonstrated The centrosphere in metazoan cells is never, to our knowledge, a bladder-like structure, the sponge Golgi apparatus lies around a centrosome, from which the flagellum arises, and there is no evidence that the centrosphere in sponge cells is more fluid than the rest of the cytoplasm—but quite the reverse

The line of evidence that both the cortex of the contractile vacuole and of the Golgi apparatus are not visible *in vivo* need not detain us

Similarly, the view that the cortex of the contractile vacuole and the Golgi apparatus have similar powers of secreting substances, is not one of much value The whole discussion comes down to the fact that the metazoan Golgi body, and the cortex of the contractile vacuole, both have the power of reducing osmium tetroxide There are a number of lipoid substances which share this power, and much attention should not be given to this faculty alone

Coming down from pure hypothesis to facts, what we know at present is this a perfectly normal Golgi apparatus has been shown to exist in certain Sporozoa —in Adelea, Coccidium, Aggregata, Adelina, and Haplosporidium. The methods used for this demonstration have not succeeded so far in revealing a similar structure in any ciliate, though the contractile vacuole cortex can be blackened by osmic acid In this laboratory we have tried amœbæ, and many ciliates both free living and parasitic, and we have come to the conclusion that a Golgi apparatus probably does not exist in the Ciliophora and Rhizopoda examined by us.

Finally, we prefer to believe that the Golgi apparatus arose in some primitive flagellated organism in direct association with the blepharoplast.

The Interaction between Silica and Electrolytes in its Relation to Theories of Soil Acidity.

IN a note to NATURE (Dec 2, 1922) some experiments were described in support of a theoretical explanation advanced in an earlier paper (*Phil Mag*, vi 44, 338-45) regarding the nature of soil acidity. Joseph and Hancock (T 1923, 123, 2022), however, state that "pure silica produces no effect on a solution of an acid," and that the adsorption we reported "would not be observed if the silica were more highly purified." We have since repeated our experiments

with hydrated silica (obtained in three different ways), which was purified with the greatest care We have been able to confirm our previous observations that hydrated silica adsorbs acids and that electro-osmotic experiments show that anions are preferentially adsorbed, but we have also found that the samples of silica we used before contained alkali, and gave a much higher value for the amount of acid adsorbed The adsorption of oxalic acid can be very easily demonstrated in view of the simplicity with which it can be volumetrically estimated 10 gm. of air-dried hydrated silica obtained from the hydrolysis of pure silicon tetrachloride can retain, even after repeated washings, oxalic acid equivalent to 10 c c of N/100 permanganate solution

It has been suggested by the writer (Trans Far Soc., vol 18, part 3, p 316) that the increase in P_H of the drainage water from Dartmoor may be attributed to the adsorption of acids by the siliceous beds over which the water passes It is quite easy to demonstrate in the laboratory that a solution of hydrochloric acid, after filtration through a Gooch crucible of fused silica containing air-dried hydrated silica (from silicon tetrachloride), immediately shows an increase in P_H, amounting to more than one unit, indicating a diminution in concentration of more than 90 per cent (*e g* from 3·4 to 4 6)

It has also been stated by Joseph and Hancock that interaction between silica and salt solution is of a chemical nature, as the residue gives an alkaline reaction on removal of the salt It appears to us that this is not the only possible way of accounting for the production of the alkali (cf "Adsorption by Sugar Charcoal," Bartell and Miller, J Amer Chem. Soc , 44, 1922, 1866 , 45, 1923, 1106 , 46, 1923, 1130)

Attention may be directed to the fact that the concentration of the acid liberated by a potassium chloride solution of definite concentration depends on the relative amounts of silica and solution, as also on its previous history. It would appear from the observations of Joseph and Hancock (*loc cit* p 2023) that whereas a sample which has been previously treated with hydrochloric acid gives an extract having a P_H value equal to 3 96, samples which have not been treated with acids give extracts having P_H value equal to 5 33 (or 5·55) under identical conditions The variation in concentration of the hydrogen ions of more than twenty times is extremely difficult to explain in terms of a chemical reaction We would also like to mention the observations of Jordis and Kanter (*Z anorg Chem* , 35, 20, 1903), who, from the difficulty in removing the last traces of hydrochloric acid from silica, concluded that silica forms traces of a complex acid similar to hydrofluosilicic acid.

Further experiments with precipitates like barium sulphate show perfect analogy with the reactions we have observed with silicic acid In these instances, possibility of a chemical interaction between an acid and a neutral salt is very remote In this connexion an interesting observation may be recorded, which to the writer's knowledge has not been recorded before If barium sulphate is precipitated from the interaction of solutions of potassium sulphate (P_H = 6·8) and barium chloride (P_H = 6 6), the liquid shows either an alkaline or an acid reaction according as potassium sulphate or barium chloride is in excess. The acidity or alkalinity may be as high as that indicated by P_H values of 2 and 11 respectively. This reaction appears to offer a clue to the elucidation of the nature of " hydrolytic " adsorption.

Helium and Airships.

IN a recent article on the British dirigible programme (NATURE, December 6, p. 842) it is stated " The United States naturally hold for themselves the only supplies of helium . ." Of course, it must be admitted that the United States authorities, ever since 1918, have pressed with vigour the investigation of their resources of helium, its production and use At the present time the two large dirigibles, the *Shenandoah* and the *Los Angeles*, are inflated with helium Processes of repurifying the gas in them have been devised and applied A more efficient and cheaper method of production than the present Linde process has been worked out by the U S Bureau of Mines, and much valuable scientific data have been accumulated.

It should not be forgotten, however, that Prof. J C. McLennan's investigation in 1916–1918 (see NATURE, August 12, 1920, p 747) showed that helium could also be produced in Canada, and an experimental extraction plant was successfully operated in Calgary, Alberta, for a few months until financial support was no longer forthcoming Since that time, the Canadian Department of Mines, in the course of a general investigation of natural gas in Canada, has confirmed and brought up-to-date the facts concerning the helium resources of Canada Although few gases have been found with so high a helium content as the richest American natural gases, it is believed that commercial sources are available To prove this, the re-establishment of an experimental helium extraction plant in Canada is essential In this plant the best process for treating the different types of Canadian natural gas could be determined, and the actual cost of commercial production could be found The helium produced, until such time as it was required by the authorities, would be of great value to supply to the many university and industrial research laboratories throughout the Empire which are needing it for experimental purpose

In connexion with a later paragraph of the same article, referring to the useful life of German airships and the interest with which the progress of the *Los Angeles* (ZR3) and the new British craft will be observed, no reference is made to the great success already obtained with the helium-filled *Shenandoah*, which has now been in commission since the summer of 1923 In this period it has made many long voyages, including one transcontinental trip of more than 9000 miles Although torn from its mooring mast with the framework damaged and two gas bags ripped, during a severe storm in January 1924, it eventually returned to its hangar A hydrogen-filled ship subjected to the same conditions would probably have been destroyed. Molecular Dimensions of Celluloid.

MAY I amplify and comment upon Mr Garnett's letter in NATURE of January 10, page 51 ? I have often been impressed, more particularly during the last few months in collecting material for a small book on cellulose ester solutions, with the want of precision shown by physicists in defining the material used in experiments on nitrocellulose and its technical derivatives. Two eminent examples will suffice. My friend Prof. Coker entitled a most important paper, which he published in collaboration with Mr. Chakko, " The Stress-Strain Properties of Nitrocellulose and the Law of its Optical Behaviour,"

whereas the material on which his experiments were carried out was xylonite or celluloid containing at least a fifth of its weight of camphor and rather more than that proportion of camphor by volume (Phil Trans, A, vol 221, pp 139-162) Another old friend and teacher, Prof Filon, in a paper which he and Mr. Jessop published on the stress-optical effect in transparent solids strained beyond the elastic limit (Phil Trans, A, vol 223, pp 89 125), after deducing the existence in xylonite of a mixture of two materials with different elastic and plastic properties (page 112), speaks in his summary (paragraph (2), page 123) of "nitrocellulose under simple tension" The distinction between xylonite and nitrocellulose in this relation is really important, as it is probable that the elastic and stress-optical properties of nitrocellulose alone would be markedly different from those of xylonite

Mr Garnett refers to celluloid as the basis of photographic film. This is true, but photographic film is quite different in its composition from celluloid in the more massive form, such, for example, as was used by Prof Coker and Prof Filon Not only is the nitrocellulose in celluloid film more highly nitrated, but the proportion of camphor is smaller Even celluloid film, however, does not contain nitrocellulose so highly nitrated as to correspond with what used to be called cellulose trinitrate. This would contain 14 1 per cent of nitrogen, while the nitrocellulose in cinema film usually contains from 12·0 to 12 5 per cent of nitrogen Lastly, having supervised the manufacture of a certain amount of a substitute for celloidin during the War, I should naturally agree that it is a carefully purified product, but I should not like to say that it approaches to a single chemical substance

The analysis of celluloid, provided the camphor used in its manufacture is optically active, is not exceedingly difficult and can be carried out with moderate accuracy, and it would add greatly to the ultimate value of physical measurements made with the material if its composition were always given In the instance which forms the subject of Mr Garnett's criticism, one would like to know not only the chemical characteristics of the nitrocellulose used, but also as many physical properties as possible, more especially perhaps the fluidity-concentration curve in two or more chosen solvents. It is greatly to be desired that all researches on colloid materials should seek to correlate at least two different properties.

The Need for a Universal Language.

I READ President Coolidge's address and Prof Gardner's letter on this subject in the *Times* of November 21, 1923, and, now, your report of Prof R G. Kent's article (NATURE, January 3, p. 23), with interest, but there are two points connected with the matter to which attention may usefully be directed. One of the principal causes of the neglect of Latin and Greek in schools is the world-wide recognition of the importance of a knowledge of the so-called "modern languages." This is a blind argument It is as if a student, desiring to acquaint himself with the contents of the top shelves in a library, deliberately ignored and neglected the ladder by which they are reached, and tried to get at them by jumping. Those who are old enough to have been at school in the days of compulsory Latin and Greek amply realise the enormous value of even an almost forgotten grounding in the classics, in the acquisition of any foreign language—this point requires no labouring I wish to point out the great value of having at some time been taught the phonation of an unfamiliar text, like Greek, when one comes in later life to study any Oriental language—or, for obvious reasons, Russian The mind is no longer terrified by the aspect of unknown characters, and thus the first great, and often repellent, difficulty is recognised as being really of little account

A still more important point arises in connexion with the periodically recurring agitation for a "Universal Language" The obvious fallacy of founding such "languages" as Volapuk, Esperanto, Ido, and the others upon the native language of their protagonists requires no argument The result is that each country pleads for its own universal (?) language, and we are back again where we started from

But Latin is, and always has been, *the* universal language Its claims are fully set forth in the report of the Committee of the British Association (1921, p 390). I cannot, however, agree with the "Conclusion" of the Committee Down to, and even in, modern times, knowledge intended to be of world-wide distribution has been, and is, conveyed in Latin —and the worse the Latin is, the easier it is to understand. I am not one of those who plead the rarefied joy of reading the great Latin authors in the original tongue—we have not the time, and existing translations are amply satisfactory—but we do want a language of universal intercommunication, and the appalling Latin of the Roman Church (cf the Bollandists' "Lives of the Saints") is entirely sufficient for the purpose I have proved this in many obscure corners of the world, using a doctor, chemist, priest, or librarian—any one in a black coat, in fact—as an interpreter

If this were once realised and recognised, I see no reason why within a short time one may not ask of any wayfarer in a Magyar town

"Quae est via ad vapor-stationem?"

And receive the reply "Primus ad dextram et tunc tertius ad sinistram"

Atque Felix semper ambulabat.

(O, Shade of Arnold!)

Balfour Stewart's Advances in Radiation Theory.

THE extremely interesting notes by Sir Arthur Schuster in a recent number of NATURE (January 17, p 87) may possibly leave with the ordinary reader an impression that Balfour Stewart's contributions to the establishment of the laws of natural radiation were slighter than was actually the case The considered opinion of the late Lord Rayleigh, set out in *Phil Mag*, 1 1901, pp 98-100, or "Scientific Papers," IV. pp. 404-5, can hardly be gainsaid. In Stewart's discussion of radiation in an isolated enclosure containing moving bodies, his expressed conviction, that the second law of thermodynamics is only satisfied through the action of mechanical forces necessary to maintain the motion, is only turning round the other way the considerations employed by Boltzmann and by Wien long after, who by means of these mechanical forces (namely, the reaction of radiation pressure) combined with the second law of thermodynamics, deduced the law of structure of natural radiation. Reference may also be made to footnotes appended to the reprint of Stokes's cognate papers in "Math and Phys. Papers," IV especially p. 136

JOSEPH LARMOR.
Cambridge, January 16.

The Tsetse-Fly Menace in Tropical Africa.

By Major A. G. CHURCH, D.S.O., M.C.
(Member of the East African Parliamentary Commission).

THE inauguration of a campaign against the tsetse-fly in Tropical Africa is long overdue. Tropical Africa is becoming progressively important as a source of food-supply and raw materials for the Eurasian and American nations The world at large, therefore, cannot contemplate with equanimity the domination by "fly" of a large proportion of the most fertile lands in the tropics. What is most disquieting, moreover, is the fact that the area under "fly" is increasing and not diminishing Hitherto, no colonial government has either had the means or has considered it worth while to adopt methods for its extermination like those employed by Gorgas in the Panama Canal zone against the mosquito Yet, in effect, the ravages due to glossinæ are, in some respects, more deadly than those due to anophelines Malaria has been largely robbed of its former terrors It can be prevented and cured But up to the present no certain preventive remedy has been found for human sleeping-sickness and animal trypanosomiasis, although cases of sleeping-sickness have been cured by atoxyl, Bayer "205," or tryparsamide

From reports supplied to the Parliamentary Commission by the scientific staffs of the five East African territories, Northern Rhodesia, Nyasaland, Tanganyika, Uganda, and Kenya, it appears that the fly-belts are continuous from the Egyptian Sudan to Southern Rhodesia Two-thirds of Tanganyika are under "fly," and this area is increasing owing to the encroachments by fly over the contiguous cultivated areas.* Fly areas which a few years ago were confined to the north-eastern district of Northern Rhodesia now extend as belts through Nyasaland to the lake and make the southern and northern movement by land of cattle from the important district of Mombera an impossibility Most of the islands on Lake Victoria Nyanza are depopulated, some compulsorily as in the case of the Sese[1] islands, others voluntarily, owing to the ravages of sleeping-sickness.

The members of the Parliamentary Commission, on their journey from Dar-es-Salaam along the central Tanganyika Railway, were struck by the desolation of a long stretch of country between Kazi-Kazi and Tabora, a country which was formerly thickly populated. Along the eighty miles of road from Tabora to Kahama men and women passed in procession carrying head-loads of ground nuts to Tabora market, primarily due, not to the conservatism of the native, but to the impossibility of using ox-wagons in a fly district. The following day they passed along thirty miles of road approaching Shinyanga without seeing a native or a head of cattle, although the route lay through a district of exceptional fertility Half the journey from Shinyanga to Mwanza provided the same melancholy testimony of the disastrous effect of tsetse In one sultanate in this district the population has gone down from thirty thousand to three thousand in the past few years, due entirely to the destruction of cattle by this insect pest. For the natives, who still measure their wealth by the number of cattle they possess, will not remain in a district where the cattle die. Mr. Swynnerton, Chief Game Ranger to Tanganyika Territory, states that the fly is known to have advanced in seven places in one district during the past year The largest cattle area in Tanganyika Territory is threatened by the advance of *Glossina swynnertoni*.

It is, however, not merely the destruction of cattle, but the effects which such destruction has upon the natives themselves and the country, which are now causing the gravest concern to the authorities Major G. St J Orde Brown, an administrative officer with years of experience, attributes to this agency the degeneracy and degradation of the north-eastern branch of the Yao tribe compared with the main tribe The loss of their cattle has led to the breakdown of tribal customs and the decline in their morality There is another serious factor which must be taken into account The lines of communication for the greater part of East Africa must necessarily pass through fly areas. For some years at least the economic products must be carried over roads. At the present time most of the roads are unfit for motor transport The use of ox-wagons becomes, therefore, a matter of first importance, but at present their use is circumscribed by the fly-belt. In the past two or three years there has been a remarkable increase in the productivity of the native in most parts of East Africa. If this is to be maintained, the districts through which the roads pass must be cleared of fly; for the present method of head porterage is totally inadequate, and traders are already complaining that their up-country stores are filled to overflowing.

It must not be imagined that this problem has not been viewed with the gravest concern by medical and veterinary officers on the spot, or that the home authorities are not aware of the menace of the tsetse-fly. The work of Sir David Bruce is well known So long ago as 1902 the Royal Society sent out a commission to investigate trypanosomiasis. Much individual and team work of great importance has been done since then. In 1914, Dr. J. O. Shircore, in a contribution to the *Bulletin of Entomological Research*, formulated a plan for the extermination and control of fly. He showed that the primary fly centres were to be found where moisture and game persisted throughout the year. They were to be found, in other words, where light forest, short grass, open glades, and water existed. Furthermore, from these primary centres the fly extended to secondary centres, and bush cover was essential as a communicating link between primary and secondary centres. He suggested that the secondary centres must first be attacked by cutting off their bush connexions with the primary centres, and that when the primaries had been isolated, wholesale and extensive burning during the dry season should be undertaken on a heroic scale. Unfortunately, the War intervened, and it was not until recently that Mr. Swynnerton's energies were applied to the methods suggested by Dr. Shircore. But Mr. Swynnerton has gone further. There is no ques-

[1] The natives are now being encouraged to return to these islands.

tion about the dependence of the fly upon blood. The further assumption was made that the fly cannot exist without game. Mr. Swynnerton has shown this to be untrue. In the Dar-es-Salaam district there is no game, but there are three kinds of fly known to exist. The fly apparently feeds upon human beings and animals indiscriminately.

Mr. Swynnerton proposes to exterminate the fly by bush burning, and he has already achieved a considerable measure of success in the Shinyanga district. There he was fortunate in obtaining the collaboration of a native chief of character and understanding and energy. Makweia, the chief in question, once convinced of the importance of fly extermination, called his people together and informed them that they were to take part in a campaign against a more insidious enemy than man, that they must discipline themselves and respond to instructions as if they were engaged in tribal warfare With the assistance of fifteen thousand natives, Mr Swynnerton was able to undertake bush clearings by means of burning and cutting on a vast scale, with the result that a large area of country will this year be under cultivation and a hitherto desolated district be re-populated and re-stocked.

In the neighbouring province of Uganda, Drs. Carpenter and Duke, and Mr Fiske, are carrying out research of the greatest importance Only a few years ago, owing to the death of more than two hundred thousand natives of sleeping-sickness, Sir Hesketh Bell removed the remaining population from the lake islands and the lake shores, an extremely costly undertaking and one which has been responsible since for much unrest among the detribalised natives Mr Fiske is carrying out single-handed an entomological survey of Uganda Dr Duke is at the moment engaged upon the important task of classifying human and animal trypanosomes and the connexion between human and animal trypanosomiasis. Dr Lamborn, who has been working in Nyasaland, has for some time been engaged in the task of breeding parasites which attack the tsetse-fly with the object of exterminating tsetse by this measure

It is clear, however, that unless all these territories make a co-ordinated and combined effort to deal with the tsetse-fly menace, the achievements in one territory will be negatived by the indifference in others. It will be useless, for example, to exterminate the fly in Uganda and Tanganyika portions of the Lake territory, if Kenya undertakes no similar campaign in the Kavirondo district Sir Robert Coryndon, Governor of Kenya, has stated that "the leading experts who deal with the problems of sleeping-sickness and tsetse-fly control are servants of Uganda, and there is little organised or encouraged co-ordination or exchange of views between them and their technical colleagues in Kenya and Tanganyika Territory." In Kenya colony, as a matter of fact, there is practically no staff available for work in connexion with sleeping-sickness or animal trypanosomiasis.

There is every indication, however, of a changed attitude. In every territory the Governors impressed upon the members of the Parliamentary Commission the necessity for a co-ordinated plan of campaign in the interests of their territories At the present time the Imperial Bureau of Entomology is engaged in formulating a plan of campaign of research into tsetse-fly problems. It is quite obvious that the problems are so vast as to be beyond the capacity of less than ten men to deal with them As Dr. Andrew Balfour said in an address at the Anderson College of Medicine on October 14, 1924. "We are not yet certain as to whether *Trypanosoma gambiense* and *T. rhodesiense* are the same parasite or different species. We still quarrel over the vexed question of the big game, or perhaps one should say the wild animals, as reservoirs of infection We know precious little about immunity to the disease; we are not at all sure as to the habits of Glossinæ, and we are still trying to discover which is the best drug and how we can best prevent this mysterious complaint" The matter is one of such great importance that it is to be hoped that Major Ormsby-Gore's suggestion, that a large working commission of experts be appointed to undertake the necessary research work in consultation with the men on the spot, will be acted upon Such collaboration must form the basis of any heroic measures for tsetse-fly extermination.

Biographical Byways.[1]

By Sir ARTHUR SCHUSTER, F.R.S.

5. LUDWIG BOLTZMANN (1844–1906).

I DID not know Boltzmann intimately, but can tell of some incidents in his life and quote from passages in little-known publications, which mark his impulsive and vigorous character, and illustrate some features of his personality that would be missed by any one acquainted only with his scientific writings. As a young man twenty-six years old, who had only published one or two minor papers, Boltzmann called on Königsberger, then professor of mathematics at Heidelberg, mentioning incidentally that he had discovered an error in one of Kirchhoff's mathematical papers. Königsberger told him that this was a good opportunity of becoming personally acquainted with one of the great men of the time. "Call on Kirchhoff," he advised. "Lead the conversation to the subject, and explain the nature of his error."

Boltzmann acted with characteristic impetuosity. Within an hour Kirchhoff, who always took a great pride in his accuracy, came rushing into Konigsberger's room in a state of extreme agitation "A most distressing thing has just happened to me," he exclaimed. "A young man, of whom I know nothing, enters my room, and before he has time to shut the door behind him, calls out: 'Herr Professor, Sie haben einen Fehler gemacht!'" I give the tale on Konigsberger's authority.

Boltzmann made his reputation during sixteen quiet years at Gratz, but it was a grief to him that his lectures did not attract a more numerous audience, and he was always looking out for a university where

[1] Continued from p. 127.

budding mathematicians were as plentiful as chemists or lawyers. He went to Munich; next to Vienna, but still not being able to satisfy his ambition he was drawn again to Germany, the country towards which he had strong political leanings. He received an offer of a professorship at Berlin, and I was informed by one in a position to know, that the faculty of science at that University received a series of telegrams and letters, few of the latter being dated, some accepting, some refusing, and no one knew in what order they were dispatched. Ultimately, the negotiations were broken off, and Boltzmann went to Leipzig, but he soon longed to return to Vienna. That University would have welcomed his return, but the Emperor declined to call him back, on the ground that an Austrian subject who had accepted foreign service was disqualified from ever again finding employment in his dominion. Mr. von Hartel—who at the time was Austrian Minister of Public Instruction—told me how for a considerable time he stood helpless between two fires: on one side the insistence of the University which wanted Boltzmann, on the other the obstinacy of the Emperor who remained firm in his refusal. At last von Hartel decided to make a final effort, and asked the Emperor for permission to put a hypothetical question. This being granted, the question put was: "If your Majesty's favourite ballet dancer were to run away, and after a year's absence wanted to return, would you have her back?" The Emperor admitted that perhaps he might.

"I beg to submit," said the Minister, "Boltzmann is to the University what your favourite ballet dancer is to you"

Francis Joseph laughed and gave in.

I do not tell the story merely as an amusing episode, but because the image of Boltzmann's ungainly figure trying to practise ballet steps recalls to my mind the occasions—fortunately rare—when Boltzmann indulged in humorous writing. He had travelled much, visiting America, Constantinople, Athens, Smyrna, and Algiers, and in one of his writings tells us how he had always declined to publish an account of his experiences, but that after returning from a lecturing engagement at the Berkeley University in California, the temptation proved too strong, and an article appeared under the title of "Reise eines deutschen Professors in Eldorado." His jokes are driven into us with hammers. Eating and drinking, followed by drinking without eating, form a favourite subject, because to him—as he says—the most important consideration in travelling is to keep one's digestion right. But he might have spared us the gross and unrepeatable allusions to the poisonous effects of pure water and the boast that his otherwise good memory for figures fails when he tries to remember the number of glasses of beer he has imbibed! The astonishing part of his recital is, however, its want of accuracy In an account of a dinner party given in his honour at the country seat of a wealthy lady near San Francisco, he tells us how it began with blackberries, which were followed by oatmeal: "an indescribable mixture of paste and oats, which might be used for fattening geese in Vienna were it not that the geese would refuse to eat it." The enumeration of subsequent dishes makes it clear that it was really dinner and not breakfast that was meant. On scientific matters also he falls into error, as when he tells the reader that the moons of Mars were discovered at the Lick Observatory.

In great contrast with this heavy and vulgar joking, the other matter contained in the volume of popular writings shows us Boltzmann as a highly cultivated man, enthusiastic about poetry, fond of music, not averse from expressing an opinion on art, and with a leaning towards metaphysical speculations. An article on flying written in 1894 is specially interesting, and the following passage shows considerable foresight:

> "It is scarcely doubtful that a dirigible air-ship would create an expansion of intercommunication compared with which that due to the introduction of railways and steamers is negligible. Our armies of to-day would be as helpless against the dynamite thrown down from flying machines as those of Rome would have been against breechloaders The customs' regulations would either have to submit to unthought-of alterations or to be abolished altogether."

Astonishing, as coming from an Austrian, is the German chauvinism to which Boltzmann occasionally gives expression. It appears in his article on aviation, and in a passage in the description of his Californian journey After criticising the Berlin Academy and expressing regret that, since the death of Helmholtz and other distinguished Germans, American students prefer to study in Cambridge and Paris rather than in Berlin, he adds that the United States, and with it the whole world, will suffer in consequence

On scientific matters his judgment is nearly always fair and uninfluenced by national feeling, at any rate so far as Great Britain is concerned. Here is an example of his style of writing when he is carried away by his subject:

> "A mathematician will at once recognise the authorship of the writings of Cauchy, Gauss, Jacobi or Helmholtz, just as musicians will distinguish between Mozart, Beethoven and Schubert on listening to the first few notes of a composition. Perfect elegance of construction, though occasionally supported by weak foundations, belongs to the French; the greatest dramatic vigour to the English—and above all to Maxwell. Who does not know his dynamical theory of gases? First the variations of velocities are deployed in majestic array; next enter from one side the mathematical conditions and from the other the equations of central motion. Higher and higher rises the chaotic flood of formulæ until suddenly four words resound: 'Let n be 5,' and the malignant demon V vanishes, just as in an orchestra a wild overpowering bass may suddenly be reduced to silence. By a magic wand, an apparently hopeless confusion is reduced to order. There is no time to explain why one or the other substitution is made; let him who does not feel it in his bones put away the book. Maxwell is not a conventional musician who has got to explain his notes; obediently his formulæ deliver torrential showers of results, until we reach the final surprise effect. The problem of the thermal equilibrium of a heavy gas is solved, and the curtain falls. I recollect Kirchhoff's

remark to me: 'This is the way to deal with gas theories!'"

It is not perhaps fair to examine this passage too closely, as a certain amount of poetic license must be forgiven—but Maxwell did not write, "Let n be 5"; he wrote, "It will be shown that we have reasons from experiment to believe that $n=5$." Sixteen words instead of four; but scientific accuracy has no chance when rhetorical effect is in danger, as the late Lord Rayleigh remarked to me when I criticised a statement of a distinguished relative of his.

Shortly after his final return to Vienna, Boltzmann committed suicide. With him passed away a man of great intellectual power and a fascinating personality. His predilection for Schiller's poetry indicates a strain of morbid sentimentality, and if his humour was somewhat primitive and his technique crude, he paid dearly for his disappointments in life.

The Talking Film.

By Dr. E. E. FOURNIER D'ALBE.

THE demonstration of the De Forest phonofilm at the Royal Society of Arts on November 26, 1924, and its recent exhibition at the Royal College of Science during the Physical and Optical Societies' Exhibition, showed that the old problem of producing a motion picture endowed with its original sound effects has been brought within hail of a perfect solution

As Mr. C. F. Elwell remarked in the course of the demonstrations, the De Forest phonofilm was preceded by many partial solutions of the same problem.

The first "talking picture" was known as the "cameraphone"—the method employed being to make the motion picture while a stock wax cylinder type of record was played The actors sang, or pretended to sing, and the camera photographed the lip motion. The novelty of this method made it popular for a time.

The "kinetophone" of Thomas A. Edison was the next step in advance. Better results were obtained for the reason that the phonograph record was made simultaneously with the making of the motion picture negative. The synchronisation of the sounds with the lip motion was good, but the reproduction of this synchronisation was difficult, as so much depended upon the skill of the operator, who generally had another man to start the phonograph record If mechanical or electrical means were supplied it was difficult to keep the phonograph record and the film exactly in step. If a portion of the film became mutilated the difficulties became greater. Notwithstanding these objections the "kinetophone" enjoyed quite a large measure of popularity. But this popularity waned, and finally no more was heard of this method.

It became evident that no solution would be practically workable until a perfect synchronism between sound and movement could be automatically established. It was, therefore, necessary to look for other methods of reproducing sound. Among these the most promising was Ernst Ruhmer's "photographophone" of 1907, in which a "speaking arc" projected light through a slit on to a moving photographic film. The audio-frequency fluctuations of the arc were thus recorded as a series of lines stretching across the film in a direction normal to its displacement, and Ruhmer succeeded in reproducing the original sound by transmitting a beam of light through this record to a selenium cell.

It was a modification of this method which Dr. Lee de Forest used for his talking motion picture. In common with Berglund and other experimenters, he confined the photographophone record to a narrow portion of the standard one-inch film as used in cinema theatres. But his method of producing the record has many original features. He uses a double-button ("push-pull") microphone with a duralumin diaphragm between the two buttons. Such a microphone is capable of carrying 20 milliamperes. It is placed

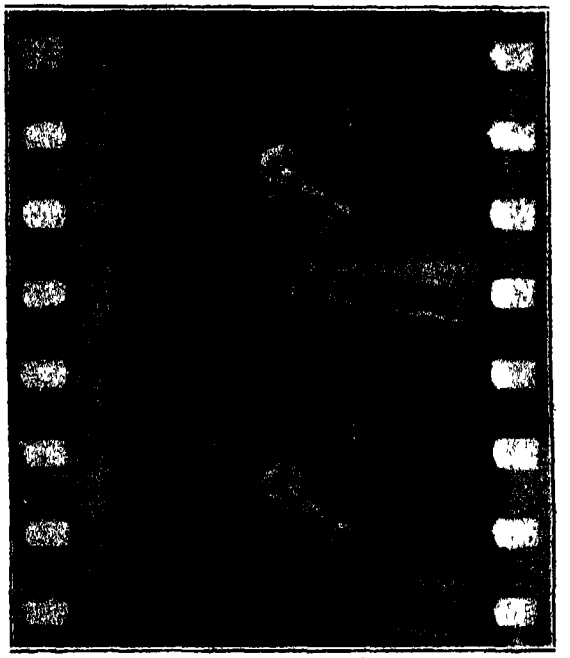

FIG. 1.—Enlarged photo of piece of film showing a banjoist performing. The cloudy strip at the left of the photograph is the music record

about 5 feet from the speaker, and responds to all frequencies from 30 to 7000 per second.

An even better device is a condenser microphone with a capacity of 4 milli-microfarads, which is found capable of a range of 25 to 8000 vibrations per second.

The distortionless amplification of the electrical pulses yielded by the microphone is nowadays a comparatively easy matter, thanks largely to Dr Lee de Forest's own previous inventions.

The next stage is the conversion of the electric pulses into fluctuations of actinic light. This conversion is neatly accomplished by means of a vacuum tube in which an electrode covered with barium dioxide discharges a current of some 5 milliamperes under a pressure of 150 volts through helium at 100 mm. pressure. This vacuum tube is called a "photion." It responds instantaneously to the variations of the

amplified microphone current, and as its glow is of a highly actinic wave-length it produces a well-marked effect upon the film, upon which it shines through a fine slit.

It remains to reconvert the photographic record into sound. For this purpose Dr. de Forest prefers to use photo-electric cells instead of selenium, mainly on account of their more constant zero, though it is difficult to see why that should be of any consequence in the case of intermittent light. Of the various forms of photo-electric cells he prefers T. W Case's "thalofide" (thallium oxy-sulphide) cell, which has a resistance of from 5 to 500 megohms, and works best with some 140 volts on the electrodes.

The moving film passes a fine slit, 0·038 mm. wide and 2·3 mm. long, illuminated by a small incandescent lamp The electric fluctuations produced in the circuit of the photo-electric cell are excessively minute on account of its high resistance, but four or five stages of amplification suffice to enable them to operate a loud-speaker, and the actual volume of sound heard at the demonstrations showed that not much difficulty need be anticipated on that score The remaining difficulty appears to be the distortion introduced by the loud-speaker. Whether that can be entirely eliminated remains to be seen. The rapid progress made in the construction of loud-speaking telephone receivers in recent times gives room for optimism in this direction. In the banjo solo (see Fig. 1) no distortion was perceptible, but President Coolidge's speech was marked by an exaggerated American accent, most of which must have been due to the manner of reproduction. This fact may obtrude itself less upon an American audience than upon Britishers, but if it were to be perpetuated, the vogue of the American film in England would be seriously jeopardised.

It has often been objected that nobody wants the talking film, that silent film acting is an art in itself; that the film has an international appeal, which would be lost by introducing speech and local accent, and that the art and training of even the greatest film "stars" would become useless if the film were to throw off its mantle of silence But the most probable issue is that the talking film will develop its own art and its own industry in its own way, and although it will no doubt evolve its own conventions and limitations, it is likely to win a permanent place among the amenities of civilisation.

Obituary.

Abbé Rousselot.

THE Abbé Rousselot passed away on December 16 last. Born in 1846 at St Cloud (Charente), he was ordained in 1870 and became one of the teachers in the Petit Séminaire de Richemont Leaving his pastoral work on account of his health, he devoted himself to language studies under Brachet, Bréal, and Bailly. He became convinced that "phonetics should take as its basis not dead texts but the living and speaking man" In his peregrinations from parish to parish he became keenly observant of the fact that "sounds change with perfect regularity from one region to another", he came to believe that "phonetics could be something more and better than a descriptive science of spoken sounds, that it ought to be geographical" Noticing the differences in pronunciation among three generations of his own family living together, he got the idea of genealogical phonetics This thought led to the foundation of the science of experimental phonetics

Coming to Paris in 1880, Rousselot was initiated into questions of Romance linguistics by Gaston Paris and Michel Bréal, to the physical sciences by Branley and Becquerel, to physiology by Déjerine, and to fine instrument work by Koenig Finding it impossible to detect the finer details of spoken sounds by the ear, he complained to Gaston Paris, who said, "Only mechanical registration will give you accurate knowledge. Attempts have been made in Marey's laboratory. Go and see!"

In 1886, Rousselot devised an electric speech recorder with which he made investigations of his native dialect. In 1889 the first course in experimental phonetics was given at the Institut Catholique de Paris. In 1891 he obtained his Doctorat ès Lettres before a committee hostile to experiments—the first doctorate in experimental phonetics. He was the inspirer of *La Parole* and later the founder and editor of the *Revue de Phonétique* (1911–1915). His great work, "Principes de phonétique expérimentale," was finished in 1908.

In 1897, G. Paris and Bréal succeeded in founding a laboratory of experimental phonetics at the Collège de France; it was annexed to the chair of comparative grammar (Bréal) and Rousselot was made its director In opening the laboratory, Prof. Bréal did not hesitate to declare that "the moment has arrived when one could no longer think of phonetics as anything else than experimental"; he proclaimed that from now onward "it would be necessary to collect facts instead of announcing *a priori* principles"

In this heroic age, the Abbé and his pupils worked with insatiable ardour at inventing apparatus, developing methods, and collecting facts. They had to face the opposition of the whole world of linguists, grammarians, and philologists, but with ready pens they fired their bombs of explosive facts at the army of opinion and guesswork.

Rousselot had several admirers and friends of the older generation outside France. Foremost among them was the linguist and phonetician, Viëtor of Marburg, who invited Rousselot to lecture there and insisted on introducing experimental methods in a modest way. Under his auspices a phonetic cabinet was established with Calzia, a pupil of Rousselot, as chief. The speech pathologist Gutzmann developed an extensive laboratory on Rousselot's lines in Berlin in connexion with the speech clinic. Coming into phonetics from another side, I had the privilege of spending a few weeks in Rousselot's laboratory in the early days; his spirit and his methods have been the inspiration in all I have attempted since.

Few of Rousselot's pupils have succeeded in following him. The environment has usually not been favourable, and they have seldom had the inspiration that

leads to self-sacrifice for an ideal. The most successful pupil is probably Prof. Calzia in Hamburg, who, in a favourable environment created by Meinhoff, has built up the most completely equipped laboratory of the present day. A favourite pupil, Prof. Chlumski, has now a laboratory in the University of Prag. His latest pupil and assistant, the Abbé Millet, has been appointed to take charge of Rousselot's laboratory.

In establishing experimental or laboratory phonetics, Rousselot's scientific influence has been decisive. In France, laboratory work has been begun at Grenoble and Montpellier Work with Rousselot's methods has also been introduced into the Sorbonne. In Germany, the large laboratory at Hamburg and the pathological speech laboratory at Berlin are based on his methods; smaller beginnings are found in other universities. In the United States I built up an extensive laboratory at Yale University, but the work was dropped after my departure. The demand for this work in that country is now pressing, but no men can be found who have learned the methods In England I have for twelve years conducted researches on speech in nervous diseases, using Rousselot's graphic method, and I scarcely need say that in Vienna the work is based on Rousselot's ideas and methods.

In one way it might be said that Rousselot just lived to see the realisation of his ideal as expressed by Prof Bréal. The adjective "experimental" need no longer be used; there is no other kind of phonetic science. This means that in investigating living speech, all judgments by the ear become quite subordinate to the study of registrations But no one could for a moment think of any antagonism between the phonetics of present-day speech and the science of historical phonetics treating of sound change in the past. In fact, what experimental phoneticians have accomplished in their domain is a small matter in comparison with the magnificent work of past and present linguists. What Prof Bréal meant to point out was probably that when the historical phoneticians wish for explanations of the past facts of sound change, they must seek the sources of similar processes in living speech; this information can be obtained only through experimental phonetics. It behoves experimenters, however, to recognise that in this direction they have been able to advance only a very small way.

Experimental work was begun by men in other sciences, such as Brücke, Donders, Hermann, Helmholtz and others—nearly all physiologists, but the unification of effort into a science was the work of Rousselot. He is fully entitled to be called the "Father of Experimental Phonetics." E. W. SCRIPTURE.

SIR GUILFORD L. MOLESWORTH, K.C.I.E.

THE death on January 21 at the age of ninety-six of Sir Guilford Lindsey Molesworth removes one whose name has long been a household word among engineers. To few it is given to become a leader in his profession, but Sir Guilford Molesworth not only rose to distinction and became the president of the Institution of Civil Engineers, but he also compiled a standard work of reference which has been carried into the remotest corners of the earth. Published first in 1862, his "Pocket Book of Engineering Formulæ" passed through no fewer than twenty-four editions before 1900. A "Molesworth" was to be found in the pocket of practically every engineer, and its pages have been thumbed in many a difficult situation, knowing that its contents could safely be relied on

Born in Southampton on May 3, 1828, nine years before Queen Victoria came to the throne, Sir Guilford was the son of the Rev. J. E. N. Molesworth, vicar of Rochdale, grandson of John Molesworth the mathematician, and was a descendant of the first Viscount Molesworth, created in 1716 He was educated at King's School, Canterbury, and at the College of Civil Engineering, Putney, and then was apprenticed to Fairbairn, the leading engineer of his day. He gained experience in railway engineering on the London and North-Western Railway, and London, Brighton, and South Coast Railway, and during the Crimean War was employed in Woolwich Arsenal. In 1859, at the age of thirty-one, he went out to the East in connexion with the first railway in Ceylon: that from Colombo to Kandy. Three years later he became chief resident engineer of the line, and in 1867 Director of Public Works From Ceylon, in 1871, he passed into the service of the Indian Government as technical adviser on railways and held that position until 1889, receiving the honour of knighthood in 1888 He had seen active service in Afghan and Burma, and after his retirement was employed in various government missions, such as reporting on the Uganda Railway He also became known as a writer on the decimal system, bimetallism, taxation, and other subjects In 1904, at the age of seventy-six, he was chosen to succeed Sir William White, the great naval architect, as president of the Institution of Civil Engineers, and his address contains an admirable summary of the public works of India. Prefacing his remarks by a saying attributed to Macaulay to the effect that "a broken head in Coldbath Fields created greater excitement in England than three pitched battles in India," he reviewed the progress of the irrigation works and the railways of India, and referred to the Indian Government as "the purest administration in the world" Speaking of the resources of India, he said its coal fields covered an area of 35,000 square miles and contained some 20,000 million tons of coal.

A man of extraordinary physical energy, when in Uganda in 1899 Sir Guilford cycled 46 miles on the hottest day of the summer "without experiencing any fatigue," and in the early part of the War, when well over eighty years of age, he served as a skilled mechanic in one of the munition shops of Messrs Vickers at Crayford.

WE much regret to announce the death on January 26, at the age of seventy-one years, of Sir James Mackenzie, F.R.S., honorary physician to his Majesty in Scotland. Sir James will be remembered as a pioneer investigator on cardiac disease, and only recently was awarded the Charles Mickle Prize offered by the University of Toronto for the best work to advance sound knowledge of a practical kind in medical art or science during the past ten years.

Current Topics and Events.

DURING the past week there have appeared articles upon a method of permanently moth-proofing wool, by the use of a substance of undisclosed composition, the product of a German dye firm These were supplemented by a lecture given at Australia House on Friday, January 23, in which the merits of this process were elaborated. The tests made were on wool and furs, large quantities of eggs of the clothes moth being employed upon treated and untreated material under identical conditions. Two forms of treatment are used—one a water-soluble material for goods that can be treated with water, the second, soluble in benzene and suitable for the dry-cleaning process It is claimed that after the water process, dry cleaning will not affect the goods, but dry-cleaning articles already treated by the dry-cleaning method will remove the protective substance. Prof H Maxwell Lefroy has been good enough to favour us with the following comments upon the process. "The nature of the water-soluble substance has been actually known in England for more than a year tests have been carried out in London with this material for eighteen months, and two new classes of moth-proofing substance have been discovered, which have all the merits of this material and in addition are far less costly and far simpler to apply As these are the result of inquiry instigated by commercial interests, it is not possible to disclose their composition, but it is unfortunate that the columns of reputable daily papers should be available for a description of a secret preparation under the guise of 'news,' made by a foreign firm In this particular instance, scientific research in England appears to be ahead of that in Germany but, as usual, has not been backed by resources in any degree comparable to those employed by the firm in Germany now vigorously exploiting a method that has already been superseded. One may anticipate the adoption of the German substance in view of the vigorous publicity and the greater commercial enterprise in such chemical production"

A COMPREHENSIVE scheme for the publication of abstracts of biological research on an international scale has been developed in the United States and has received general support from scientific institutions in that country The proposals were put before the British Association at Toronto last summer, and a committee of the Royal Society is also considering the matter. The subject was discussed at a representative meeting of British zoologists held in the rooms of the Zoological Society of London on January 10, when the following resolution was passed unanimously —"This meeting of British zoologists is of opinion that it is in the highest degree desirable that an effort should be made to extend the system of publishing comprehensive abstracts of zoological literature, and we desire to place on record our great appreciation of the work that has been done to this end by the American Committee for *Biological Abstracts*. We are, however, also of opinion that the scheme that has recently been submitted for our approval is open to serious objection in various directions. Only some of these need here be mentioned, namely: (1) The magnitude of the work involved appears to have been under-estimated. (2) The financial arrangements so far made public are obviously quite inadequate for the purpose, which is a most serious point, it would be folly to assume that any publication of abstracts in pure science can be made self-supporting, and no scheme of this kind should be put into operation until satisfactory arrangements have been made for some permanent endowment (3) The proposal to publish the abstracts of the whole of biological literature in a single journal is unsatisfactory; such a journal would be extremely cumbersome and highly inconvenient for all classes of workers Bearing in mind the probable great increase of literature in the future, a much sounder plan would be to institute separate journals dealing with convenient sections of scientific work (4) The abstracts will be very much shorter than those now being published in this country, and this brevity will seriously detract from their value to most workers (5) The estimates for indexing are entirely inadequate (6) No provision has been made for the utilisation or co-ordination of the various biological abstracting organisations that already exist in this country and deal adequately with several branches of science; apparently it is proposed to reduplicate their work, but in a less useful form In the circumstances we consider that this scheme requires drastic revision"

THE application of science to problems connected with the cotton industry formed the subject of Dr A W. Crossley's discourse at the Royal Institution on Friday, January 23 Nearly every branch of science has its bearing on the cotton industry. Botanically, much work is being done on the structure of the cotton hair itself and its relation to the various processes, such as spinning, that it goes through during manufacture From an engineering point of view, it is extraordinary that no great invention has been made in regard to cotton machinery for more than fifty years, and the British Cotton Industry Research Association has already under consideration important modifications in one machine. At the Shirley Institute laboratories, too, new light has been thrown on mercerisation, for which it has been found there is a definite limiting botanical factor. Much valuable work has just been carried out on problems connected with bleachings Cotton well bleached should be white, but should not have suffered any deep-seated chemical changes such as would affect its physical properties or lower its strength; also bleaching is carried out by means of oxidising agents, and great care has to be taken as they attack the cellulose to form oxycelluloses. Unlevel dyeing may be a result. The chemical tests that are used for determining the extent of this attack have been investigated, and it has been discovered that the slightest change of acidity or alkalinity of the liquor plays an important part. The application of physics has produced a number

of important instruments for testing the regularity of yarns, their resistance to wear and to oscillating tensions, as well as their tension in the loom. In a special regularity tester, the irregularities in a yarn are magnified 18,000 times by a shoe riding over it and a system of indicators and mirrors which produce on a moving bromide strip a photographic record of every minute change of twist and so act as an index to the action of the spinning machinery on the yarn. The doubling twist can also be measured by the instrument Here another important achievement has been attained, for in conjunction with a special photometer which compares degrees of brightness, the right doubling twist that should be given to a singles yarn to produce the most lustrous effect has been discovered

An interesting exhibition of photographs, paintings, and drawings from the third Everest Expedition is now being held at the Alpine Club Gallery, Mill Street, W In addition to views of Everest, the photographs by Capt J B L. Noel show something of the interesting country through which the expedition passed Among them is a photograph of a gigantic figure of Buddha, more than forty feet high, from the Shekar Monastery It is said that within this figure there are stored many thousands of precious stones and other treasures. The oil paintings and drawings by Mr. Francis Helps, apart from their artistic merit, which is considerable, are of scientific value as a record of racial types and costume. They depict Lepchas, Tibetans, and Sikkimese. A portrait of the Maharanee of Sikkim and of a lady in full Tibetan dress are both very effective. The latter wears the full Tibetan head-dress with false hair. A painting of a Lepcha woman has the old costume, now discarded, although the traditional dress of the men, also shown, is retained. There is a very fine representation of a Red Lama in ceremonial dress with striking and strongly marked features. A Bhutia girl with pronounced Mongolian characteristics, while not in itself unpleasing, in the heaviness of the type serves as a foil to the other female heads The artist has shown great skill in catching the differences in type and expression of the various races.

A dispatch from the Cairo correspondent of the *Times* in the issue of January 20 records some noteworthy results obtained by the members of the Boston-Harvard Expedition this season in their excavations on the limestone plateau east of the pyramid of Cheops at Giza. In clearing the Royal Cemetery of the Fourth Dynasty, boat-shaped cuttings were found in the rock foundation of the chapel of Cheops which had served as receptacles for the funereal boats of the dead king and his queens. In one which has been uncovered, the bottom was made to fit the shape of the boat, and one of the slabs of the covering is still in position. The most important find consisted of two small tombs of the Sixth Dynasty belonging to two priests, Qa'ar and Iduw, his son. In the tomb of the former the entrance leads into a hall in which stand five figures each representing Qa'ar in one of his official capacities, with a little figure of his son Iduw. This tomb is of an entirely new type. The tomb of Iduw also contains six life-sized figures, five of Iduw himself and one of his son. On the walls are skilfully carved reliefs which include four scenes of men and women mourning, a subject rare at this period. What is described as the gem of the whole find is a stele of limestone, coloured to represent granite, on the right-hand wall. Starting high up on the wall, it reaches only half-way to the ground The rock beneath the lower edges has been hollowed out to form a rectangular niche in which the upper part of Iduw's body is carved life-size, as if emerging from the rock, with outstretched arms, palms upward, as though in readiness to receive the offerings the priests placed on the offering stone which lies in front It is an astonishing break from the formalism of Egyptian art, remarkable in the Old Empire

In a lecture given in the Royal Exchange on January 20 on the Evolution of the Steamship, to the members of Lloyds' Students' Society, Eng.-Capt Edgar C. Smith, now the official guide lecturer at the Science Museum, South Kensington, suggested that if the members should be ever in need of technical information they could not do better than visit the Science Museum, where they would find models and diagrams in profusion and, moreover, the best technical library in Great Britain. In the course of his lecture, Capt. Smith said that the Science Museum deserves the support of every shipbuilder, shipowner and engineer in the country It is much more than a museum; it is the nation's permanent Palace of Engineering. As compared with similar institutions, the Science Museum may be said to show how men have made their fortunes while the art galleries show how they have spent them It was Sir Richard Tangye, whose first success came with the construction of the hydraulic jacks used to push the *Great Eastern* into the Thames, who gave Birmingham its beautiful picture gallery, while it was Samson Fox, the inventor of the corrugated flue used in marine boilers, who built the Royal College of Music at South Kensington. Bessemer, Hughes, Mond and many others had left large fortunes, but in the matter of legacies the Science Museum had been treated like a spendthrift and cut off without a shilling Though the engineering exhibits at the Museum are in a fair way to be properly housed, the same remark does not apply to the naval collections, and what is wanted now at the Museum is a National Gallery of Ships and Shipping worthy of the greatest port in the world, of the nation itself, and of our glorious heritage of the sea.

The presidential address to the Royal Meteorological Society was delivered on January 21 by Mr. C. J. P. Cave, who took as his subject, "The Present Position of Meteorology and Meteorological Knowledge." The Royal Meteorological Society celebrates its seventy-fifth anniversary this year In looking back Mr. Cave stated that great progress has been made in the past 25 years, largely stimulated by upper air research. Meteorology is at a disadvantage compared with other sciences; the number of posts open to meteorologists is very limited; and support for the Society has to come largely from amateurs.

The Society ought to encourage education in meteorological science But it is not only elementary meteorology that should be encouraged ; there is a vast scope for research in the science , forecasting is only one of its branches, and except in the matter of forecasting, meteorology in Great Britain is the worst endowed of all the sciences. Is it too much to hope that some great company or some public-spirited individual may come forward to endow a chair of meteorology in one of our universities and to make provision for research The Royal Meteorological Society is, so to speak, in a position of trust for meteorology, being the only independent body in the country especially devoted to that science It is true that there is the Meteorological Office, but its position at the present time is an unfortunate one , its future is uncertain In the past the Meteorological Office was directly under the Meteorological Committee, which administered a Government grant. Soon after the War, the Office was placed under the Air Ministry It seems a grave anomaly that the Meteorological Office, which deals with problems of the greatest importance to many Government departments and to many public bodies, should be solely under the direction of the Air Ministry, more especially when there is in the Department of Scientific and Industrial Research a very suitable body under which it might have been placed

SENATOR MARCONI has been elected an honorary member of the Institution of Civil Engineers.

DR. J H JEANS will deliver the sixteenth Kelvin Lecture of the Institution of Electrical Engineers on Thursday, February 5, at 6 o'clock The title of the lecture will be " Electrical Forces and Quanta." At the beginning of the meeting a statuette of the late Sir Joseph Wilson Swan will be presented to the Institution by Mr R K Morcom

APPLICATIONS are invited by the Scottish Society for Research in Plant-breeding for the directorship of research, in succession to Mr. J M F Drummond, who was recently appointed Regius professor of botany in the University of Glasgow The applications, with statements of qualifications and experience (in each case seven copies), must reach the Secretary, 3 George IV. Bridge, Edinburgh, by March 14, at latest

THE British Non-Ferrous Metals Research Association, 71 Temple Row, Birmingham, is inviting applications for three junior research posts, namely, a physical chemist or metallurgist (for work on atmospheric corrosion), a metallurgist or chemist (for the study of the wastage of copper locomotive fire-box stay rods), and a metallurgist with good physics training (for the study of zinc and high-zinc alloys and their workability) The latest date for the receipt of applications is February 9

THE four-hundredth anniversary of the death of Vasco da Gama, who was the first to reach India by the Cape route, and died on Christmas Eve, 1524, is being celebrated at Lisbon. The *Times* correspondent reports that at a reception held at the Palace of Belem on January 24, representatives of twenty-six governments presented their credentials. On January 25 there was a service at Belem Cathedral, and the blessing of the sea at the place whence da Gama sailed.

SIR JOSEPH J. THOMSON has been awarded the Faraday Medal by the Council of the Institution of Electrical Engineers. This medal is awarded not more frequently than once a year, either for notable scientific or industrial achievement in electrical engineering or for conspicuous service rendered to the advancement of electrical science, without restriction as regards nationality, country of residence, or membership of the Institution The present award is the fourth which has been made

THE Buchan prize of the Royal Meteorological Society was awarded to Mr W H Dines, at the annual general meeting held on January 21 The prize, now awarded for the first time, was recently founded to commemorate the late Dr Alexander Buchan, who did much to advance the interest of meteorology in Scotland and was intimately associated with the work done on Ben Nevis The award was made to Mr W. H Dines for his recent papers on radiation read before the Society Mr. C J P Cave, the president of the Society, in making the award, recalled the pioneer work which Mr Dines had done in the investigation of the upper air before he turned his attention to the problems of radiation

THE Gold Medal of the Royal Astronomical Society has been awarded by the Council to Sir Frank Dyson, Astronomer Royal, for his general contributions to astronomy, and in particular for his researches on the proper motions of stars. The medal will probably be presented at the ordinary meeting of the Society on June 12 At the annual meeting, to be held on February 13, Prof Eddington, Dr Jackson, Mrs Maunder, and Prof Milne will speak on the progress of astronomy during the past year , Prof Fowler and Prof Newall will speak on the forthcoming meeting of the International Astronomical Union at Cambridge , and Dr Dreyer will give a short account of Tycho Brahe's observations, methods, and results

THE National Institute of Agricultural Botany is now prepared to accept entries for its fourth series of yield and quality trials of new varieties of potatoes from breeders who are willing to entrust the Institute with the marketing of their productions on a profit-sharing basis. The trials are planned to last for five years, at first in Scotland only, but in the later years also in the English potato districts Only those varieties which do sufficiently well in the trials will be placed on the market. Full particulars of the conditions of the trials can be obtained from the Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge. Applications should be made not later than February 28.

SCHOLARSHIPS, each of the annual value of 300*l.*, are being offered by the Grocers' Company for the encouragement of original research in sanitary science. There will also be an allowance to meet the cost of

apparatus and other expenses in connexion with the work. The tenure of the scholarships is one year, with possible renewal for a second or third year. Applications must be sent before April 1 to the Clerk of the Grocers' Company, Grocers' Hall, London, E.C.2, from whom a form of application and further information may be obtained.

CERTAIN of the members of the staff of the Rothamsted Experimental Station, Harpenden, Hertford, are available for a limited number of lectures to Chambers of Agriculture and Horticulture, Farmers' Clubs, Agricultural Societies, Farm Workers' Associations, and similar bodies, on the work being carried on at the Station. The subjects include various aspects of manuring and agricultural chemistry, physics and botany, the use of insecticides and fungicides, bee-keeping, and so on. All communications regarding lectures should be addressed to the Secretary of Rothamsted Experimental Station.

ACCORDING to the Report of the Council of the Zoological Society of London for December, the number of visitors to the Society's Gardens in Regent's Park during the year 1924 reached the total of 2,057,146—the largest number in the history of the Society, and an increase of 444,021 as compared with the previous year. The number of visitors to the Society's Aquarium since its opening in April reached the total of 567,936. The number of fellows elected and readmitted during the year 1924 was 876, an increase of 374 as compared with the previous year, and a record never before reached in the history of the Society.

THE collection of antique microscopes, about 400 in number, formed by the late Sir Frank Crisp, Bart., is to be offered for sale by auction at Stevens's Auction Rooms, Ltd., 38 King Street, Covent Garden, W.C.2, on Tuesday, February 17. Catalogues can be had from the auctioneers.

IT has been suggested recently that Messrs. Oertling, Ltd., are importing parts of German balances and merely assembling them in Great Britain. We understand that this is quite untrue. All Messrs. Oertling's balances are manufactured entirely at the firm's works in Turnmill Street, E.C.1.

Our Astronomical Column.

THE SOLAR ECLIPSE OF JANUARY 24.—Preparations were made at Greenwich for observing the first contact by the Innes method with several instruments, but thick clouds interfered. There were frequent glimpses of the partially eclipsed sun, but nothing could be done except to note the change of illumination and of the colour of daylight. The latter changed markedly near greatest phase, the cause, doubtless, being the absorption of light of short wave-length near the sun's limb. There were some beautiful spectral colours on clouds near the sun.

It is very welcome news that the conditions at the Yale Observatory, Newhaven and elsewhere on the east coast of the United States are described as perfect, and the photographs obtained there should be of great interest. The following time determinations of totality are given in the telegrams (the figures are the corrections to the times computed from the almanac data): Yale $+4^{sec}$, Buffalo -2^{sec}, Ithaca $+5^{sec}$, Poughkeepsie $+3^{sec}$, Newhaven $+5^{sec}$, Long Island $+3{\cdot}6^{sec}$, Mean $+3^{sec}$. The almanacs used a correction of $+8{\cdot}0''$ to Brown's longitude (corresponding with $+7{\cdot}0''$ to his mean longitude) but used no correction for the sun which requires about $+1''$, or $+2^{sec}$ in the time of eclipse. Hence it would appear that the correction applied to the moon was within $1''$ of the truth, but perhaps slightly too great.

The country round New York was covered with snow, and the passage of the moon's shadow over this white surface, which was clearly seen, must have been a striking sight. On the whole, the weather in the United States seems to have beaten expectations, which were not high owing to the season.

OCCULTATION AND LUNAR ECLIPSE.—It is worth directing attention to the fact that the occultation of Aldebaran on February 2 is the last (at least for the neighbourhood of London) of the series that have been going on for some three years. It will be followed by a blank period of nearly sixteen years. Disappearance is at $23^h\ 54^m$, 4 hours west of the meridian, and reappearance 53 minutes later. In view of Prof. Brown's appeal, and the facilities for accurate time afforded by wireless, it is hoped that it will be extensively observed.

The lunar eclipse of February 8, lasting from $20^h\ 8^m$ to $23^h\ 15^m$, will be favourably visible in Great Britain, the moon being high up. Three-quarters of the moon's diameter will be obscured, and it may be possible to form some idea of the colour and illumination of the portion in the shadow. These are now believed to depend on the meteorological conditions prevailing at the regions where the moon is in the horizon, so that they give a sort of integrated effect of terrestrial weather.

THE NEW WOLF PERIODIC COMET.—Although this object was of mag. 17 on January 13, Prof. M. Wolf was able to make some interesting observations of its physical structure. "It was a small nebulous object of fan or sector shape, $\frac{1}{2}'$ in width, somewhat less in height, with nuclear condensation in the point of the sector which was towards S.S.E." This structure and the cometary nature of the orbit leave no doubt that it is correctly classed as a comet. The following orbit is by Dr. A. C. D. Crommelin from the photographic positions of December 22, January 13 (Heidelberg), and December 26 (Greenwich):

T	1925, January 23 9624 G.M.T. (new)	
ω	184° 8′ 27″	1924·0
Ω	260 36 36	
i	23 7 9	
ϕ	21 57 47	
μ	472·951″	
Period	7·5022 years.	

An ephemeris is of little use, for very few instruments can reach so faint an object.

There is a very near approach of the orbit at aphelion to that of Jupiter. There is no near approach at the next aphelion (nor has there been any in recent revolutions), but there will be a fairly close approach at the next aphelion but one. Similar elements were obtained by Herr Kahrstedt, who gave the period as 7·43 years.

Research Items.

THE CHRONOLOGY OF CENTRAL AMERICA.—Mr. R. C. E. Long in *Man* for January examines the bearings of the historical evidence upon the correlations of Mayan and Christian chronology put forward by Dr. Morley and Mr. Bowditch respectively. The argument turns upon whether it can be shown that Nahua influence existed in Chichen Itza before its overthrow by Hunnac Ceel, governor of Mayapan, or whether the Nahua buildings in the city—some of the greatest in Yucatan—were erected after that event, as Morley holds. A date deciphered by Morley on a ball-court—a typical Nahua structure—at Uxmal proves the existence of the Nahua in Yucatan before the date to which Bowditch assigned the fall of Chichen Itza. If, then, it can be shown that Nahua influence in Chichen Itza also precedes the fall, that in the light of the Uxmal date would afford strong support to the Bowditch dating, but if it can be shown to be later than that event, it supports the Morley correlation. It seems unlikely that the buildings at Chichen Itza which show Nahua influence would have been erected in a period of great wars, such as this is known to have been, when, as Morley thinks, the city had been handed over to Mexican mercenaries. A conclusive piece of evidence, however, is a passage in the Chilan Balam of Chumayel which states that Hunnac Ceel had himself once been thrown into the Cenote of Sacrifice at Chichen Itza, and that, as he had survived the requisite time, he had been taken out and worshipped. This custom of throwing victims into the Cenote was purely a Nahua practice and was introduced into Chichen Itza only after the establishment of Nahua rule. It follows, therefore, that as the custom must have been observed before the overthrow of Chichen Itza by Hunnac Ceel and not after, the date of the ball-court at Uxmal would fall into line with and support the date suggested by the Bowditch correlation.

MAGIC AND MEDICINE.—An illustrated guide to the collections dealing with medical history in the United States National Museum, Washington, has been compiled by Mr. Charles Whitehead, Assistant Curator of the Division of Medicine, and published as Article 15 of Vol. 65 of the Museum's Proceedings. These collections, which since 1916 have formed part of a larger section of the Department of Art and Industry covering the history of pharmacy, public hygiene and sanitation, are classified under magic medicine, psychic medicine, and pharmacological medicine, the last named including Egyptian, Greek, and Roman medicine, while the first covers the healing art of primitive, savage, and half-civilised man as well as the numerous survivals of primitive medicine among civilised peoples. It is naturally the most fully represented. Among the amulets or charms is a specimen illustrating the voodoo of the negroes of the United States and West Indies, which consists of a chicken feather, some human hair, a drop of blood on a rag, and a pine sliver. This is worn on the neck as a preventive of voodoo against the wearer. A number of "madstones," which, when applied to a dogbite, avert madness, have proved their efficacy in the hands of their former owners. For one, a highly polished seed of *Gymnocladus dioica*, the Kentucky coffee tree, 1000 dollars was asked, and a ball of matted hair, such as is occasionally found in the stomach of domesticated cattle and other ruminants, was said to have been used successfully in two cases. One exhibit is a section of a tree from Norfolk, Va., which had been tapped, human (negro) hair inserted, and the hole plugged and sealed with clay. Four inches of new growth formed over the plug, so that the hair must have been inserted fifty years before it was found. The operation was doubtless performed either to relieve headache, or to cause headache in the original possessor of the hair.

THE BRITISH RACES OF *ARICIA MEDON*, ESPER.—*Aricia medon* occurs in the British Isles in two distinct races, the type *medon* and the variety *artaxerxes*. The type occurs in England and Wales and the variety in Scotland and Ireland, but their areas of distribution overlap in the N.E. of England. Dr. J. W. H. Harrison and Mr. W. Carter (Trans. Nat. Hist. Soc. Northumberland, Durham, and Newcastle-upon-Tyne, N.S., vol. vi. pt. 1) have discussed the origin of these two races. They reject both the possibility of origin from an original mixed population in N.E. England, and an explanation based on orthogenetic mutations. They conclude that the variety originated in a contingent of the type isolated during the glacial period, under the long-continued influence of the refrigerating conditions that obtained at that time, and they cite the experimental results of refrigeration on other species of Lepidoptera in support of their theory. They find, moreover, that in the overlapping areas of their distribution the inheritance follows Mendelian lines.

MERISTEM GROWTH IN WOUNDED POTATOES.—G. A. C. Herklots has a paper in the *New Phytologist* (vol. 23, No. 5, December 1924) in which the cork meristem formed upon cut potato tubers under suitable conditions is used as a means of investigating certain views recently put forward (NATURE, August 16, 1924, p. 258, "Mechanism of Cell Growth") as to the influence of the external hydrion concentration upon the activity of meristematic protoplasm. Experimenting with the cut surface in contact with buffered solutions or jellies, he finds that an alkaline reaction at the cut surface favours rapid suberisation, but delays or (if beyond $P_H 8$) entirely prevents meristem formation, whilst an acid reaction at the cut surface, whilst delaying the process of suberisation, facilitates meristem formation.

A CINCHONA INSECT PEST.—In the report for 1923–24 of the Government cinchona plantations and factory in Bengal, attention is directed to the ravages of Helopeltis. On the plantations both at Mungpoo and Munsong, this pest is on the increase and the attacks have reached and maintained a severity that renders hand-picking ineffectual. The trouble is greater at lower than at higher elevations, and in certain parts of the plantations the growth of the plants is completely suspended for several months of the year. Coppicing as a preventative is beneficial in so far as the affected portions are removed entire, but the disease reappears when the fresh shoots sprout. There seems to be no satisfactory method of dealing with this insect pest. A season that is unfavourable to its development is more beneficial than all the counter measures that have been devised up to the present. In spite of these difficulties and somewhat adverse weather conditions, the plantations did well during the year under review.

ASIATIC SUCCINEIDÆ.—One of the most difficult of the families of the non-marine mollusca to deal with satisfactorily is the Succineidæ. The shells present so few salient characters, whilst far too little is known of their anatomy. All the more credit, therefore, to Mr. H. Srinivasa Rao, of the Zoological Survey of India, for the excellent little monograph he has just furnished of the Asiatic Succineidæ in the Indian Museum (Rec. Indian Mus. xxvi.). The author has

brought together all the facts he was able concerning the anatomy and habits of the members of the family as represented in the Indian Museum, and has principally utilised the jaw and radula for the purposes of distinguishing the various species. The Indian Succineidæ comprise four distinct genera: Succinea itself, which is amphibious, and three terrestrial genera—Indosuccinea, which is new, Lithotis, and Camptonyx. The type of the new genus is *Succinea semiserica* Gould, and the author has further created a few new species and varieties. There are good, clear text figures of the jaws and radula teeth and a very good photo-plate of the shells of the more important species.

RATOONED QUEENSLAND COTTON.—A short note by Mr. Frederick Summers in the Journal of the Textile Institute for December has considerable general interest. When growing wild, the cotton plant is always a perennial, but under cultivation, either because of drought or winter conditions in the resting season, or more usually because of the way in which the pests and diseases of the crop accumulate in the second and succeeding years, it is the rule in Egypt and the West Indies to remove the old stumps after the first year's crop of fruit has been gathered (NATURE, May 31, 1924, p 800) In S America, and also in Africa under native cultivation, the plants are often cut down hard at the end of the growing season, and then allowed to produce fresh shoots in the following season, in other words, treated as from time immemorial bush and woody fruits have been treated in Great Britain In the case of cotton, this process is known as ratooning, and there has been much discussion, on inadequate data, as to whether the ratooned crop, whatever its quantity, is of similar quality with the first year's yield. Fruit growers would naturally tend to assume that quality would be maintained, and one can understand that when new areas come under cultivation for cotton, the pest problem being still little developed, the planters have a natural tendency to follow the practice of ratooning. Queensland growers have done this, although in 1923 for a short period the process was made illegal, as the result of inquiries by the Queensland Ministry of Agriculture as to the esteem in which ratoon cotton is held in Great Britain. This ban has again been removed, and Mr. Summers now reports a careful test of the quality of ratooned fibre as against the normal crop, and it is interesting to see that this examination tells heavily against the ratooned product. This conclusion is of great scientific interest and contrasts strongly with our experience of many perennial plants when brought into cultivation Mr. Summers emphasises the fact that generalisation must not be based upon these Queensland samples alone, but they certainly raise the problem in a very definite form, and both its scientific interest and commercial importance should mean that further opportunities will be taken of comparing authentic samples of ratoon and normal cottons.

THE JAPANESE EARTHQUAKE OF 1923.—The investigation of the disastrous earthquake which devastated Tokyo in September 1923 is still proceeding, but some preliminary reports have already appeared. In the *Geographical Journal* for January, Dr. C. Davison has an article bringing together the information on the subject at present available, in which he discusses, among other aspects of the earthquake, its origin. The epicentral tract of the earthquake was of unusual size and may have covered so much as 2000 square miles, including the whole of Sagami Bay. Its area may even have been 4700 square miles. The cause, at least in part, is to be sought in the movements which produced remarkable changes in the floor of Sagami Bay. These changes were very considerable, and although no fault scarp has been discovered on the floor of the bay, a vast block or series of blocks seem to have subsided. A remarkable feature of this subsidence is that the movements on the floor of the bay have affected very slightly the surrounding coasts. The greatest elevation of the sea-bed was more than a hundred times that on land, and the greatest depression of the sea-bed was more than 1600 times that on land Moreover, the centres of elevation and depression are very close to one another. There is also evidence that the movements on the sea floor were not confined to the time of the earthquake but continued in the same directions for so long as five months, and even now may not be at an end.

MAGNETIC SURVEY WORK IN THE UNITED STATES.—The results of magnetic observations made by the United States Coast and Geodetic Survey in 1923 are published as No. 268 of the survey publications. Five magnetic observatories continued in operation throughout the year, namely, Cheltenham, Md., Sitka, Alaska; Honolulu, Hawaii, Vieques Island, P R; and Tucson, Arizona Their records have furnished the data for reducing to monthly means the values of declination obtained from field observations The magnetic survey of Florida was completed and a survey of North Carolina was made. Declination observations were made at a large number of stations along the southern and south-eastern shores of Alaska in connexion with the triangulation. Tables are given of the year's observations at various stations, and the report concludes with descriptions of the stations sufficiently detailed to enable them to be located even if the marking on the ground should be destroyed

ROTATORY DISPERSION.—The thesis on "The Chemical Significance of Optical Dispersion," on which Dr. Harold Hunter was recently awarded the degree of D Sc (Lond), has been printed and published (London: Battersea Polytechnic, Battersea Park Road, S.W 11; price 7*s* 6*d*) The thesis is a critical account of the recent position of a question which has formed the subject of considerable discussion both pre- and post-War. It presents in a convenient and accessible form the author's own personal contribution to that discussion and his comments on the views of other workers in the same field. There are very few points in the thesis which call for criticism, the principal one being perhaps the statement (p. 89) that "the rotatory dispersion equation of Drude" "suffers from the defect" that "it does not take into account the degradation of the light energy in the phenomenon of absorption," since this "defect" does not exist in Drude's original equation, but only in the simplified equation which alone is quoted by Dr Hunter. On the other hand, a partial transposition into italic type is justified as a tribute of admiration for the neat statement (p. 49) that "One of the consequences of improvements in chemical technique is that *the dynamic isomerism of to-day becomes the static isomerism of to-morrow.*"

THE CONDENSATION AND RE-EVAPORATION OF ACTIVE HYDROGEN.—In an interesting paper (*Zeitschrift für Elektrochemie*, Nr. 21/22, pp. 504-508, 1924) Fritz Paneth discusses the properties of active hydrogen and describes experiments carried out in association with K. Peters. The monatomic form (H_1), produced at low pressures by glowing wires and electric discharges, is readily adsorbed and is condensed on the walls of glass vessels cooled by liquid air, the activity disappearing on re-evaporation. At high pressures another modification is produced,

usually regarded as tri-atomic hydrogen (H_3), in conformity with the observations of J. J. Thomson and Aston on positive rays. H_3 is less strongly adsorbed than H_1 and can pass through glass wool. It is generally recognised by the production of hydrogen sulphide, when it is passed at a very low temperature over powdered sulphur. Wendt and Landauer have described an investigation in which they appear to have been successful in producing not only condensation but also re-evaporation of H_3 without change of form, and, considering the substance analogous to ozone, they suggest for it the name "hyzone." Two new methods are now described in detail for the production and study of this active modification of hydrogen. In the first, hydrogen is passed over a glowing Nernst filament, and in the second, through a heated capillary tube of palladium. The results are believed to prove that active hydrogen so produced may be condensed and re-evaporated without loss of activity, and further, that its constitution must be H_3 and not H_1. Experiments are to be continued with the view of producing the active modification in greater quantities.

THE ISOTOPES OF MERCURY.—An interesting suggestion is made by Dr F. Stumpf in the *Zeitschrift für Physik* of December 12. He directs attention to the facts that Aston has found the atomic weights 204, 202, 200, and 197 for the isotopes of mercury, and that the last number is almost identical with the atomic weight of gold. Although among the radioactive elements there are cases where different elements have the same atomic weight, this is not true for the other, non-radioactive, elements; and the author considers that it is possible that the 197 isotope was really gold and not mercury. Apparently the intensity of the 197 line was not very different from that of the others, so that it can scarcely have been due to gold existing originally as an impurity in the mercury. It is suggested that gold may have been produced from the mercury in the experiment in a similar manner to that in which Miethe claims to have caused this transformation. It might be possible to obtain evidence of this by receiving the positive rays on a plain sheet of glass or of quartz, instead of on a photographic plate; with a long exposure the glass might be coloured red with colloidal gold at the point in question. In Miethe's experiment parts of the discharge bulb were coloured red.

PROTECTIVE COLLOIDS.—A paper on colloidal protection, read by J. Alexander before the American Section of the Society of Chemical Industry last May, is published in *Chemistry and Industry* (Review) for December 19, 1924. The technical use of protective colloids has been known since antiquity. Thus the Chinese used glue in the manufacture of ink to deflocculate the lamp-black, and the ancient Egyptians used gum (probably acacia) for the same purpose. The protective action was recognised by Meyer and Lottermoser (1897). A protector may be defined as a substance which opposes the aggregation of molecules or particles into larger groups; according to Bechold, the protective action is consequent upon the adsorption of a layer of the protector at the interface between the dispersed and the dispersing phase. This layer is exceedingly thin, since it does not diminish the Brownian motion of the particles, and there is no ultramicroscopic evidence of its existence. Brief descriptions and applications are given of plural, auto- and cumulative protection.

PYROPHORIC ALLOYS.—The production and properties of pyrophoric alloys are described by Dr. N. F. Budgen in the *Chemical Trade Journal* for December 26, 1924. The "flint" of the popular type of gas-lighter was introduced by Auer von Welsbach in an interesting manner. The incandescent mantle which Welsbach introduced in 1886 contains 99 per cent. of thoria and 1 per cent. of ceria, and the large demand for thoria which it created led to the working up of the monazite sands found in different parts of the world. These sands contain about 5-10 per cent. thoria and 50-60 per cent. ceria and other rare earths, so that large quantities of rare earths, minus the thoria, accumulated at the mantle works. It was while trying to find a use for this "waste" that Welsbach discovered that alloys of iron and the cerium metals throw off sparks when rubbed with a file. The first step in the production of pyrophoric alloys is the preparation of "misch metal," which is an alloy of 40-50 per cent. cerium, 20-40 per cent. lanthanum, 1 per cent. yttrium, and small amounts of neodymium, samarium, gadolinium, etc. This alloy is then fused and mixed with an appropriate metal (*e.g.* iron, zinc, aluminium) in the molten state under a protective layer of salt or fluorspar. The best pyrophoric alloy is probably "auermetal," made by alloying up to 60 per cent. of iron with misch metal.

PHYSICAL ASPECTS OF CHEMICAL COMBINATION.—A paper on "Chemical Combination as a Dynamic Problem" by Prof. Born, of Gottingen, read at Innsbruck meeting of the German Scientific and Medical Association on September 26, 1924, is printed in *Die Naturwissenschaften* of December 26. The paper deals with the calculation of physical and chemical constants from data as to the electric charges and distances of the components of various aggregates. Thus the "lattice energies" of crystals of the rock-salt type can be calculated and give results which show a very close agreement with the observed values. In other cases, including the molecules of salt-vapours, the ions appear to be deformable, as indicated, for example, by the different refractive power of Cl' in HCl and in NaCl. A table is, however, given of the energy of formation of salt-vapours, in comparison with the lattice energy minus the heat of sublimation. The calculation of the natural free-periods of ions such as CO_3, NO_3, ClO_3, SO_4, etc., which are constant in all compounds of these ions both in solution and in solid crystals, from the charges and distances of the atoms, is also referred to.

THE PROGRESS OF DEVELOPMENT OF A PHOTOGRAPHIC PLATE.—This matter has been investigated by Mr. L. F. Davidson, of the Imperial Dry Plate Company (Journal of the Royal Photographic Society, January 1925), by watching the actual process of development under the microscope, using a high-power objective, and by taking photomicrographs at various stages. The developer was coloured so that its movement was obvious. When the developer reaches a grain, there is a definite time interval before visible action begins, and this "induction period" varies according to the developer used and according to the nature of the grain, but appears to be unaffected by grain size. Development starts at points or "centres" which enlarge and join until the whole grain is blackened. Except in the case of certain slow emulsions, the shape of the grain is changed by its development. If by reason of this change of shape it comes into contact with another grain, this second grain appears to be rendered developable. The developed grain may present an area that is smaller or very much larger than the original silver haloid grain, this alteration in area varying from 0·8 to 104 per cent. in an extended series of experiments. It was sought, though apparently not very successfully, to find some relationship between the increase in size and the character of the plate.

Prize Awards of the Paris Academy of Sciences.

AT the annual public meeting of the Paris Academy of Sciences, held on December 22, M. Guillaume Bigourdan in the chair, the prizes awarded in 1924 were announced as follows:

Mathematics.—The Poncelet prize to Ernest Vessiot, for the whole of his mathematical work, the Francœur prize to the late Ernest Malo, for his researches in algebra and arithmetic.

Mechanics.—The Montyon prize to Eugène Huguenard, Antoine Magnan, and André Planiol, for the important improvements which they have made in hot wire anemometry, the Fourneyron prize to Marcel Crozet-Fourneyron, for his historical work and inventions connected with the hydraulic turbine, the Boileau prize to Georges Routin, for his hydraulic researches, the Henri de Parville prize to Paul Bloch, for his work in ballistics, with especial reference to the projection of missiles from aeroplanes.

Astronomy.—The Lalande prize to Jules Baillaud, for his work in celestial photography, the Janssen medal to George Willis Ritchey, for his work on the construction of mirrors, the La Caille prize to Dominique Saint-Blancat, for his work on the catalogue of stars. The Benjamin Valz prize was not awarded.

Geography.—The Delalande-Guérineau prize to Charles le Maître, for his cartographical work in Algeria, the Gay prize to Émile Delcambre, for his work in topography and meteorology, the Tchihatchef prize between Ernest Benoit (1500 francs), for his work on geodesy in Indo-China, and Laurent Fiquegnon (1500 francs), for geographical work in Indo-China; the Binoux prize between Jacques Bourcart (1000 francs), for his work on the physical geography of Albania, and Édouard de Martonne (1000 francs), for his topographical, geodesic, and cartographical work in French Western Africa.

Navigation.—The prize of 6000 francs between Yves Le Prieur (4000 francs), for inventions connected with naval artillery, and Émile Georges Barrillon (2000 francs), for his study of the gyration of ships, the Plumey prize between Antoine Foillard, for his memoir on marine machines with electric transmission, and Paul Dumanois, for his volume on internal combustion motors.

Physics.—The La Caze prize to Paul Langevin, for the whole of his scientific work; the Hébert prize to Edgar Haudié, for his "Cours d'électricité générale", the Hughes prize to Alexandre Dufour, for his cathodic oscillograph; the Clément Félix prize between Jean Mercier, for his researches on the velocity of propagation of electric waves, and Pierre Fleury, for his researches on the measurement of the temperatures of electric furnaces.

Chemistry.—A Montyon prize (Unhealthy Trades) (2500 francs) to the late André Brochet, for his researches in organic chemistry and electro-chemistry; an honourable mention (1500 francs) to Isidore Lazennec; the Jecker prize to Louis Jacques Simon, for his work in organic chemistry; the La Caze prize to Camille Matignon, for the whole of his chemical work; the Cahours foundation to Suzanne Veil, for her physico-chemical researches on metallic oxides and hydroxides; the Houzeau prize to Pierre Chevenard, for his inventions of apparatus used in metallurgical research.

Mineralogy and Geology.—The Fontannes prize to Frédéric Roman, for his work in palæontology; the Victor Raulin prize to Jules Barthoux, for his memoir on the petrographical and geological study of the Arabian desert.

Botany.—The Desmazières prize to René Vandendries, for his memoirs on sexual determinism and sexuality of the Basidiomycetes, the Montagne prize to Alphonse Labbé, for his volume on the biological cycles of the Dunaliella, the de Coincy prize to François Pellegrin, for his memoir on the flora of Mayambe, from the collections of M. G. Le Testu.

Anatomy and Zoology.—The da Gama Machado prize to Christian Champy, for his researches on the spermatogenesis in *Discoglossus pictus*, the Savigny prize to Clodomir Houard, for his work on galls in Northern Africa; the Jean Thore prize to Adrien Perret-Maisonneuve, for his researches in apiculture.

Medicine and Surgery.—The Montyon prize between Victor Babès (2500 francs) for the whole of his work, Noël Fiessinger (2500 francs), for his volume on the ferments of the leucocytes in physiology, pathology, and general therapeutics, Jules Botreau-Roussel (2500 francs), for his memoir "Ostéites pianiques (Goundou)", honourable mentions (1500 francs) to Jean Baratoux, for his volume on the voice, the scientific study of its formation and emission, its diseases, to Jean Rieux, for his book on clinical hæmatology, and to Henri Glover, for his work entitled "L'auscultation électrique en physiologie et en clinique", the Barbier prize to Georges Mouriquand and Paul Michel, for their experimental work on accessory food substances; the Bréant prize (arrears) between Alfred Boquet and Léopold Nègre (2500 francs), for their work on tuberculosis, and Léon Marchand and Raymond Moussu (2500 francs), for their work on enzootic encephalitis of the horse, the Godard prize to Edmond Papin, for a memoir on endoscopy operations of the urinary passages, the Mège prize to Mme. Angélique G. Panayotatou, for her volume on the hygiene of the ancient Greeks; the Bellion prize between Paul Godin (700 francs), for his works on the evolution of growth, and Louis Bargeron (700 francs), for his researches on the lighting conditions of workshops, the Larrey prize to François Bassères, for his memoir on the medical service of the Third Army in the War.

Physiology.—The Montyon prize to André Charles Guillaume, for his memoir on the normal and pathological morpho-physiology of the small superficial blood vessels, the La Caze prize to Emmanuel Hédon, for his scientific work as a whole, and more especially for his researches on the physiology of the pancreas, the Pourat prize to André Paillot, for his memoir on the bacterial diseases of insects and their utilisation in agriculture, the Martin-Damourette prize to Henri Vignes, for his memoir on normal and pathological obstetrical physiology; the Philipeaux prize to Antoine Léon Garrelon and Daniel Santenoise, for their researches on the oculo-cardiac reflex and vago-sympathetic toxin.

Statistics.—Montyon prizes to Michel Huber (1000 francs), for the whole of his statistical work, and Émile Lambert (1000 francs), for his work in statistics.

History and Philosophy of Science.—The Binoux prize to Mme. Hélène Metzger, for her volume on chemical doctrines in France from the beginning of the seventeenth to the end of the eighteenth century.

Medals.—The Berthelot Medal to André Brochet, Louis Jacques Simon, Camille Matignon, Suzanne Veil, and to Pierre Chevenard.

The Lavoisier Medal to Joseph Achille Le Bel, for his chemical work, as it is now fifty years since the discovery of the asymmetric carbon atom.

General Prizes.—The Grand Prize of Mathematical Sciences to Paul Montel, for his researches on suites of analytical functions; the Bordin prize to Clément Vaney, for his work on the diseases of cattle; the Lallemand prize to Henry Cardot and Henri Laugier,

for the discovery and study of the linguo-maxillary reflex; the Vaillant prize to Claude Guichard, for the whole of his work in higher geometry; the Le Conte prize to André Debierne, for his work in the field of radio-activity, the Houllevigue prize between Franz Lœwinson Lessing (3500) francs), for his work in petrography, and T. Husnot, for his work in botany, the Jean Jacques Berger prize to the Institut prophylactique, the Parkin prize to Ernest Fourneau, for his work in pharmacology, the Saintour prize equally between Paul Camboué, for his researches on silks of Madagascar, and Jean Jacques Kieffer, for his work on parasitic Diptera and Hymenoptera, the Henri de Parville prize to Maurice Vèzes and Georges Dupont, for their book on resins and turpentines and the industries connected with these, the Lonchampt prize between Émile Roubaud (2000 francs), for his work on the hibernation of flies, Ernest Lobstein (1000 francs), for his biochemical researches on the tubercle bacillus, and Paul Fleury (1000 francs), for his researches on laccase, the Henry Wilde prize to Charles Mauram, for the whole of his work and for the organisation of research at the Institut de Physique du Globe, the Caméré prize to M Caquot, for his engineering work in connexion with bridge construction; the Gustave Roux prize to Eugène Séguy, for his work on Diptera, the Thorlet prize to Adolphe Richard.

Special Foundations.—The Lannelongue foundation between Mmes Casco and Ruck

Prix des Grands Écoles —The Laplace prize to Philippe Charles André Coste, the L. E Rivot prize between Philippe Charles André Coste, Lucien Félix Chadenson, Jean Charles Joseph Armanet, Vincent Louis François Pierre Bauzil

Funds for Scientific Research —The Gegner prize to Gustave Dollfus, for his geological work, the Jérome Ponti foundation to the late Hippolyte Coste, for his descriptive and illustrated flora of France, the Hirn foundation to Georges Giraud, for the whole of his work; the Henri Becquerel prize to René Garnier, for his works on differential equations

The Loutreuil Foundation —Thirty-two requests for grants from this fund were received, twenty-four grants were made as follows:

Establishments named by the founder:

National Museum of Natural History: 10,000 francs to P. Pierre Teilhard de Chardin, for palæontological researches in China, Collège de France, 15,000 francs to Henri Piéron, for the purchase of material for researches at the new physiological laboratory;

National Veterinary School at Alfort: 2000 francs to Albert Henry and Charles Leblois to pursue their researches on the etiology, pathogeny, and treatment of the parasitic skin affections of domestic animals, 3000 francs to Gabriel Petit, to pursue his researches on the radio-activation of the organism by intravenous injections of radium; 4000 francs to Gustave Moussu, for his researches on diseases of cattle and pigs; 2000 francs to François Maignon, for his work on insulin and on the mineral elements entering in the constitution of the tissue catalysts of animal and vegetable origin

National Veterinary School of Lyons: 2000 francs to Gabriel Marotel to continue his researches on two parasitic diseases of the horse and dog; 4000 francs to Joseph Basset, to finish his researches on anthrax vaccination; 2000 francs to L. Jung, to pursue his researches on the rôle of the saliva of various domestic animals in its relations with their normal food regime.

National Veterinary School of Toulouse. 2000 francs to Jules Girard and Pierre Pons, for their researches on the modifying factors of growth (temperature, special feeding, castration), 3000 francs to Albert Dalle, to finish his researches on the etiology and serotherapy of epizootic diarrhœa in newly-born calves; 2000 francs to Clément Bressou, to commence researches on the splanchnology of mammals, more particularly Carnivora, by the method of feeding and radio-opaque injections

Grants acceded to establishments admitted for one year by the president

Conservatoire national des arts et métiers 4000 francs to Léon Guillet, for the purchase of a second Le Chatelier metallographic bench.

Independent requests 1500 francs to Jean Bosler, for the *Journal des Observateurs*, 5000 francs to Jean Charcot, for the purchase of material required for the geological study of the sea floor, 3000 francs to Henri Colin, for the purchase of a combustion furnace and accessories, required in connexion with the study of new or little known carbohydrates; 1000 francs to Benjamin Jekhowsky, for assisting his work on new minor planets; 15,000 francs to Jean Mascart, for the publication of observations of variable stars; 3000 francs to the Office central de Chauffe rationnelle, for the study of the composition of a mixture of carbon monoxide and dioxide in equilibrium in the presence of carbon at various temperatures, 1500 francs to Paul Pallary, to pursue his explorations in the Middle Atlas, 5000 francs to Edmond Roy-Prémorant, for the construction of a tachylegometer invented by him; 6000 francs to the Société de Physique industrielle, for the study of the measurement of gas and steam in industry; 6000 francs to the Saint-Joseph University of Beirût, for the publication of the geological map of Syria, constructed by P. Godefroid Zumoffen.

The Bouchard foundation to Gabriel Bidon, to continue his researches on the neuro-physiology and treatment of the deformed; the Henry Le Chatelier foundation to Léon Jacqué, for researches on the fusibility of mixtures of lime, ferrous, and ferric oxides.

Medical Uses of Radium.

THE Medical Research Council has recently published, as No. 90 of its Special Report Series, a summary of reports for 1923 from research centres on the medical uses of radium. The nine clinical centres in Great Britain and Ireland which enjoy the use of radium lent to them by the Medical Research Council have been pursuing these investigations for several years, but this is the first occasion upon which the data have been arranged and used for public circulation. This is particularly welcome now, for results have been obtained which invite the careful consideration of radiologists, physicians, surgeons, and pathologists.

It may be said that the main object of the clinical investigations is to define the proper limitations of the uses of radium in the treatment of malignant disease, and to decide the best methods of treatment for any given type of this disease. Such an aim can be achieved only by very persistent work of a collaborate character continued over some years. The forms of malignant disease are so varied, the differences in reaction of the host are so large, and the factors in dosage are so numerous, that it may well be that more years will elapse before the main object of the Medical Research Council in these investigations is achieved. Yet a perusal of this report convinces the reader that a serious effort is in hand, not only to give these radiological investigations a quantitative

basis, but also to visualise the problem of radium therapy in cancer in all its complexity and yet not be baffled by it.

For some years it has been recognised that rodent ulcer is a disease very amenable to this form of therapy, and this is confirmed in the data before us. Of later years, the value of radium in cancer of the cervix uteri has been maintained, and there is a considerable mass of evidence in this report which substantiates the claim In cancer of the breast, the data show an increasing use of radium combined with surgical operation, but the full value of this combination depends largely upon the nature of the surgical operation and the extent to which it is possible to insert the radium at places of likely extension of the disease. We gather from the report that the results obtained by the use of radium in malignant disease of the mouth, jaw, or throat, continue in most cases to be disappointing This appears to be chiefly due to local anatomical and surgical difficulties rather than to any specific resistance of the tumours themselves.

Non-malignant conditions have also been investigated It is satisfactory to find in the reports from three independent centres, a practical uniformity in the dose of radium employed in the treatment of uterine fibromata and of menorrhagia, and an equal measure of success in the results.

Recognising that progress in therapy is largely dependent upon collateral researches, the Medical Research Council, through its Radiology Committee, has, from the inception of this scheme, supported such researches which have so far been of physical or biological character. Sir Ernest Rutherford reports upon the disintegration of the elements by means of alpha rays

Researches of a biological character are separately detailed as having been carried out by Mr Timbrell Fisher in osteo-arthritis, by Dr J C Mottram on changes in the intestinal tract resulting from radiation, and by Prof S Russ upon the determination of lethal doses of radiation for animal tumours

The publication as a whole is worth serious study, for it is a finger-post along the road of treatment in malignant disease While there are no extravagant claims made for it, it cannot be doubted that radium is a valuable instrument in the treatment of cancer and other diseases, and we look with confidence to the results which these investigations may provide in the near future

Chemistry in India.

THE success which has attended the inauguration of the Indian Science Congress, and the great increase in the amount of new work in chemistry which has occurred in the Indian Empire during the past ten years, has led to the establishment of an Indian Chemical Society, under the presidency of Sir P. C. Rây, with offices at 92 Upper Circular Road, Calcutta, the first number of the Quarterly Journal of the Society has now appeared

Hitherto, chemical papers emanating from India have been published either in the Journals of the Chemical Societies of London or America, or in one or other of the larger continental publications. The disadvantages attaching to this procedure became more and more obvious as the volume of new work increased, because the older Journals are becoming over-burdened, and the need for economy of space necessitated frequent correspondence between authors and editors, entailing grave loss of time in the cases of countries so far distant as India.

Apart, therefore, from the pleasure with which all British chemists will welcome this national effort on the part of India, there will be general agreement among them that the scheme of decentralisation of publications within the British Empire which it implies is the only one which can lead to the rapid and adequate publication of new knowledge and tend ultimately to the real advancement of chemistry. Optimists may dream of the time when there will be one Chemical Society and one Chemical Journal for all the English-speaking races, but until the transportation of matter can be accomplished with a velocity approaching that of light, distance must always act as an obstacle to any such plan, however desirable it may be

The new Journal is a welcome illustration of the development which has taken place in Indian chemistry during recent years There are thirteen papers, and only one of these is published under English names The remaining papers are published by Indians and come from all parts of the Indian Empire Four of them emanate from the College of Science, Calcutta, and this is as it should be, because, for many years past, this Institution has been the backbone of chemical research in India The other communications come from Allahabad, Baroda, Dacca, Cuttack, Benares, and Madras, and constitute a series of which the organising committee and editor have every reason to be proud

The Journal is well printed, and doubtless the structural formulæ, which seem, at times, to have given the printer some trouble, will improve with experience. Older chemists with impaired eyesight will probably quarrel with the colour of the cover, the printing on which is most difficult to read, but these are minor points and do not detract from the value of what is essentially a most creditable and important production. J. F. T.

The Ross Barrier.

IN a paper to the Royal Geographical Society on January 19, Mr. C. S. Wright gave an account of the Ross Barrier and the mechanism of ice movement. There is now little doubt that the barrier is bounded by high land on all sides except the north, although the ranges between Edward Land and the Maud ranges have still to be discovered. The area of this ice sheet may be given as approximately 150,000 square miles. Ample proof is forthcoming that the seaward edge of the barrier is afloat, although it is probably aground at the site of Amundsen's winter quarters east of the Bay of Whales. Observations have proved that the slope of the barrier is very slight and this must be interpreted as evidence that the barrier is afloat even quite close to its southern edge.

The barrier movement is compounded of the result due to the thrust of glaciers from the plateau on the west, south and east, and movement due to the flattening and outward extension of a thick mass of ice under its own weight. Mr. Wright gave evidence in support of the view that these two causes are roughly of equal importance. If no movement were

contributed by glacier thrust, certainly the general level character of the barrier surface would be maintained, provided that the barrier rests on a warm frictionless plane—the sea. If it rested on land, the bottom friction would be high, the temperature low, and the movement slight. On the other hand, the fact that there is little or no local thickening in the region of the outflow of land glaciers to the barrier must indicate an efficient water circulation beneath it In that case, local thickening would involve local depression and increased local melting from below; thus the general surface level would be maintained It is not possible to suppose that floating glacier tongues played no part in the formation of the barrier Such tongues are common in the Antarctic and many of them extend far out to sea.

The barrier had probably a twofold origin Numerous floating ice tongues from the large glaciers at the back of the Ross Sea were no doubt cemented together by sheets of sea-ice formed in situ in the areas between them. The latter process would entail the formation of sea-ice and precipitation of snow thereon at a rate exceeding that at which it melts below

These conditions were certainly possible during the period of maximum glaciation, even if they do not now occur Observations have shown that the rate of increase in thickness of sea-ice does not decrease largely as the thickness increases. This points to the fact that conduction of heat from below is not the sole cause of growth At present there are sheltered positions in which sea-ice can form and maintain itself for more than one year. Mr. Wright, in discussing the mechanism of movement of ice, shows how uncertain and incomplete are our data for the rate of advance of the barrier, its snowfall and contributions to its mass from land glaciers.

University and Educational Intelligence.

ABERDEEN —The University Court has resolved to institute a lectureship in clinical chemistry

Dr. Alexander Bowman has been appointed lecturer on the scientific study of fisheries

CAMBRIDGE —The Statutory Commissioners have been approached by a number of members of the Senate on the question of the retiring age for professors, which was fixed in the recommendations of the Royal Commission at 65 years The Commissioners favour the proposal that the Board of Electors to a professorship may, when a professor reaches the age of sixty-five, invite him to hold office up to an age not exceeding seventy, if it is believed that the interests of the University will best be served thereby. The Board of Electors is to be precluded from making any fresh election of a professor who is already more than 65 years of age, but if a candidate is elected who is over sixty, he may be elected to hold office up to the age of seventy.

Mr W. B. R. King, Magdalene College, has been reappointed assistant to the Woodwardian professor of geology. On the nomination of the Department of Scientific and Industrial Research, Sir Joseph Broodbank is being appointed to the committee of management of the Low Temperature Station for Research in Biochemistry and Biophysics.

The Special Board for Mathematics has reported to the Senate, asking the University to take steps to enable the Tyson Medal to be struck in bronze, instead of in gold as at present, and to be accompanied by a prize in money.

The Board for Engineering Studies has recommended certain changes in the regulations for the Mechanical Sciences Tripos, including the sub-division of certain of the advanced subjects necessary for a First Class. Thus electricity and magnetism is replaced by electric power and electric signalling, and theory of structures and strength of materials by theory of structures (civil) and theory of structures (mechanical). Mechanics of machines also figures for the first time as a separate subject. It is proposed also to establish jointly with the University of Birmingham a diploma in coal-mining engineering, for which the general course of engineering at Cambridge should count as part of the training, this course to be followed by four months' practical experience in a coal mine and a year's course in mining at the University of Birmingham.

EDINBURGH —At the meeting of the University Court on Monday, January 19, the resignation of Sir Harold J. Stiles, Regius professor of clinical surgery in the University, to take effect on March 20, was announced. The Principal expressed the great regret which was felt by the Court, the high appreciation of the eminent services which Sir Harold Stiles had rendered to the University, and the sense of the deep loss which would be sustained upon his retirement, not by the Court alone but by the University as a whole.

The Library of the Geology Department of the University has been indebted for a number of years to the late Sir Archibald Geikie for donations of valuable geological literature. The last consignment has recently been received from his daughters. This Library was gradually built up and strengthened by the Geikie brothers who in turn filled the chair of geology.

LONDON —A course of eight free public lectures on "The Chemistry of the Internal Secretions" will be given by Mr. E. C. Dodds, at the Middlesex Hospital Medical School, at 5 o'clock, on February 3, 5, 10, 12, 17, 19, 26, and March 3; one of four by Dr. J. Duncan Scott, on "The Medullary Centres," at the Physiology Department of St Bartholomew's Hospital Medical College, 6 Giltspur Street, E.C., at 5 o'clock, on February 11, 18, 25, and March 4; and one of four by Sir William I. de Courcy Wheeler, at St. Bartholomew's Hospital Medical College, at 5 o'clock, on February 16, 17, 18, and 19, on "Some Practical Considerations and Experiences in the Conservative Treatment of Fractures of the Pelvis and the Lower Extremity." Two courses of free public lectures at Birkbeck College are announced, namely, four, by Dr. G. G. Coulton, on "Medieval Education" (February 2, 9, 16, and 23), and three, by Prof. E. N. da C. Andrade, on "The Structure of the Atom" (February 5, 12, and 19). The lecture hour in each case will be 5.30, and no tickets will be required.

ST ANDREWS.—The degree of Ph.D. has been conferred on Mr. G. R Ross for a thesis entitled "The Serological and Immunological Characteristics of Tubercle Bacilli after Extraction with Fat Solvents."

APPLICATIONS are invited for two lectureships at University College, Leicester, viz. in physics and in chemistry. The applications must reach the secretary of the college by February 13 at latest.

DR. WALTER MAKOWER has been appointed professor of science at the Royal Military Academy, in succession to Prof. J. Young, retired. Dr. de Mouilpied, who was to have filled this post, resigned without taking up the appointment. Dr. Walter Makower, who was lately chief physicist to the Dunlop Rubber Company, was for many years lecturer in physics at the University of Manchester.

Societies and Academies.

LONDON

Royal Society, January 22.—H. C. H. **Carpenter** and Miss C. F. **Elam**: Experiments on the distortion of single-crystal test-pieces of aluminium. Single crystal test-pieces of aluminium can be extended up to 7 per cent without recrystallising on heating to 600° C. They will recrystallise to form either another single crystal of a different orientation or several crystals, according to the degree of strain. When a large crystal grows from a number of small ones, it has no particular orientation or relation to the direction of mechanical strain. Unless the metal recrystallises, the distortion of the crystal is not removed by heating, and unless the metal recrystallises, the heating does not remove the whole of the hardness acquired through mechanical strain. Hardening by mechanical deformation can take place independently of change of orientation. The proportional increase in hardening is greatest during the early stages of extension, but in the case of single crystals a stage is reached when the increase in hardness is approximately proportional to the amount of plastic deformation.—W. S. **Farren** and G. I. **Taylor**: The heat developed during plastic extension of metals. Hollow bars of certain metals were subjected to plastic stretching. The work done on a measured length in the middle of the specimen was measured, and at the same time the rise in temperature at the centre of the bar was recorded. The heat generated varied from 86·5 per cent. of the heat equivalent of the work done, in the case of annealed steel, to 95 per cent. in the case of single-crystal specimens of aluminium. This ratio remained constant for one material during the whole range of the extension, which in the case of aluminium amounted to more than 50 per cent. of the initial length.—J. V. **Howard** and S. L. **Smith**: Recent developments in tensile testing.—R. L. **Smith-Rose** and R. H. **Barfield**: On the determination of the directions of the forces in wireless waves at the earth's surface. The propagation of wireless waves over the earth's surface implies the reception of two or more distinct waves at an appreciable distance from the transmitting station. One of these is assumed to arrive at the earth's surface after reflection or refraction from the upper portions of the atmosphere, and an attempt is made to detect it by measuring the inclination of the wave-front of the arriving wave. Such a down-coming wave would give rise to a reflected wave which, at the earth's surface, will interfere with the incident wave in such a way as to tend to eliminate the horizontal component of the electric force and the vertical component of the magnetic force. The conductivity of the earth at wireless frequencies was determined experimentally by measuring the "forward tilt" of the waves arriving from neighbouring transmitters for a number of sites in South England. A moderately consistent value of about 10^8 (e.s.u.) was obtained, and calculations from this value show that the directions of the resultant forces at the surface will always be sensibly the same as those of a horizontally propagated wave.—D'Arcy **Thompson**: On the thirteen semi-regular solids of Archimedes, and on their development by the transformation of certain plane configurations. The thirteen isogonal non-isohedral solids attributed to Archimedes stand in close relation to the ten regular plane repeating patterns or "nets" first described by Kepler, which consist of regular and identical sets of congruent polygons. If, in the table of indices giving the number of triangles, squares, etc., found at each junction (or node), the *order* of an index be successively reduced, we pass accordingly from the plane polygonal assemblage to some one, and then to another, and so on, of the indices which characterise the several polyhedra. This transformation may be performed mechanically, by constructing a hinged net, removing (*i.e.* replacing by fenestræ) the polygons of a certain order, and allowing those which remain to slide over and so overlap one another.—F. G. **Mann** and Sir William **Pope**: 1 2 3-Triaminopropane and its complex metallic compounds.—D. L. **Chapman**, J. E. **Ramsbottom**, and C. G. **Trotman**: The union of hydrogen and oxygen in presence of silver and gold. The catalytic activity of silver is considerably reduced by heating to dull redness in oxygen, independently of the pressure of the oxygen in which it has been heated, provided that this pressure exceeds 0·005 mm. of mercury. As the pressure of the oxygen is diminished further, the activity of the treated metal falls rapidly, reaching a maximum when the oxygen pressure is 0·0013 mm. After silver has been heated to dull redness in oxygen at a pressure higher than 0·005 mm., it would seem to be covered with a thin film of silver oxide, which is a less powerful catalyst than the metal itself. Gold furnished similar but less pronounced results. In the presence of the film of silver which was formed on the surface of the glass during the experiments, hydrogen and oxygen will combine at the temperature of the laboratory.—U. R. **Evans**: The colours due to thin films on metals. Mallock has objected to the interference-theory of the colours on the grounds that he had failed to alter the colours of tempered iron by polishing the metal. It has now been shown that the colours can be changed when the thickness of the film is uniformly reduced by cathodic treatment in dilute hydrochloric acid. Raman has proposed that the colours are due to a granular structure; but the colours on molten lead can be obtained as easily when the oxide-film is molten as when it is solid, and thus the "granular theory" fails. The oxide-films have been lifted off molten lead, and examined, supported on glass, the colours by transmitted light are complementary to those by reflected light, as is to be expected on the interference view.—A. **Campbell**: On the determination of resistance in terms of mutual inductance. A new method of balancing mutual inductance against resistance is described, in which one of the conditions of balance is independent of frequency and can be set once for all, while the second condition gives a very simple relation between the frequency, two resistances and two mutual inductances.—S. **Butterworth**: On the alternating-current resistance of solenoidal coils. The general theory of eddy-current losses in cylindrical conductors is employed to establish formulæ for computing the alternating-current resistance of single-layer solenoidal coils. Two formulæ are obtained which are shown to be in reasonable agreement with observation, except when the frequency is extremely high. The formulæ should be applicable so long as the current may be regarded as having uniform distribution throughout the coil.—A. J. **Allmand** and V. S. **Puri**: The effect of superposed alternating current on the polarisable primary cell zinc—sulphuric acid—carbon. Part I.: Low-frequency current. Ten years ago Brown showed that, if an alternating current of either 100 or 12,000 periods and of suitable intensity were passed through the above primary cell, the polarisation of the latter was reduced and its current output increased. The experiments were repeated and extended, using alternating-current frequencies of 20 to 400 cycles per second, the potentials of the two electrodes being measured whilst the currents were running. The

results showed conclusively that, with such frequencies, the carbon electrode is chiefly responsible for the decreased polarisation and increased cell current The lower the frequency, the greater the effect. At the same time there were certain indications that, with higher frequencies, an effect would be produced at the zinc electrode, as observed by Brown.—R W Lunt The interaction of carbon dioxide and hydrogen in the corona due to alfernating currents of high frequency Alternating electric fields of frequency $1\cdot5\times10^7$ have been used An equimolecular mixture interacts, giving a water-gas equilibrium, which is also attained by exposing mixtures of carbon monoxide and water vapour to the discharge In no case has it been possible to detect the formation of formic acid or formaldehyde T. **Royds** The apparent tripling of certain lines in arc spectra As many spectra as possible were searched through the visible region for instances of lines becoming complex when the amount of material in the arc was increased Only seven cases were found, all of which apparently become triple with a sufficient quantity of material The Tl line 5350 passes through five successive phases, namely, broad simple reversal, triplet, doublet, a second triplet form, and a final doublet, as the amount of material in the arc burns out This line is essentially a doublet, and all the different phases can be explained as different stages in the self-reversal of the two lines of the doublet A similar explanation was adopted for the six remaining instances of apparent tripling, as all except two were found to assume a doublet form as the final phase —E. **Newbery**: Overvoltage and transfer resistance

Physical Society, December 12 —A C. **Egerton**: Numerical values of chemical constants and frequencies of the elements. The experimental evidence for the general chemical constant C_0 possessing the theoretical value ($-1\cdot589$) is collected. A linear relation between logarithm of mass and characteristic temperature is indicated —J H **Powell**: The sensibility of circular diaphragms for the reception of sounds in water The diaphragms were mounted with one face immersed in water and to the other was attached a microphonic or electro-magnetic detector They were all designed to have a frequency of 850~ under these conditions The response of the diaphragms to sounds of a single definite frequency was measured, and resonance curves were obtained from which the magnitude of the damping due to the detector was determined The corrected values for the resonance amplitude and for the persistence of vibration were consistent with those determined mathematically by Prof H. Lamb for diaphragms under ideal conditions The investigation was extended successfully to cover complex sounds or "noises" of no definite pitch —A. **Campbell**. A direct-reading frequency meter of long range A direct-reading frequency meter for audio frequencies is described It is a null instrument, reading by single adjustment, the working system embodying a new method of balancing mutual inductance by resistance The standard type has five ranges, covering from 180 to 4000~ per second, with accuracy of the order of 1 in 1000, and negligible temperature coefficient except at the lowest frequencies

Linnean Society, January 8 —E. S. **Goodrich**: On the cranial roofing-bones in the Dipnoi. A general fundamental plan of the roofing-bones of the skull can be made out, to which conform the primitive Teleostomi and Tetrapoda The earliest fossil dipnoan, Dipterus, appears to possess the usual paired frontals and parietals (still more distinct in Scaumenacia); but Messrs. Watson and Gill identify these as nasals and frontals, and believe the parietals to be represented by the median posterior occipital plate. The bones in early Dipnoi conform to the general plan; but in the course of specialisation the paired frontals and parietals tend to become reduced in size, separated in the middle line, and more and more superseded by a series of median elements, of which the median occipital is the largest and most constant —C. C. **Lacaita**. (1) A note on *Colchicum montanum* Linn The name *Colchicum montanum* must be abandoned altogether. It has generally been used for the Italian *C Bertolonii*, but *C montanum* of Linn Sp Pl. is a mixture of *Merendera Bulbocodium* with *Colchicum alpinuum*, while the specimen in herb. Linn is really *C Bulbocodium* from the eastern Mediterranean. It was not sent to Linnæus by Loefling, for it does not grow in Spain, and the sheet is marked on the back "Habitat in Morea" The spring-flowering *C Bulbocodium*, with broader leaves and more nerves in the sepals, is a distinct species from *C. Bertolonii* (2) Some critical species of Marrubium The Linnean diagnoses were written for Hort Cliff, and only repeated in Sp Pl Therefore H Cliff. specimens and not those of herb Linn are decisive, except in the case of *M hispanicum* The Adriatic plant usually called *M candidissimum* is not that of Linnæus, and must bear the name of *M incanum* Desr. True *M candidissimum* Linn is a species from Asia Minor J C **Waller** On types of electric response in plants

DUBLIN

Royal Irish Academy, January 12 —H **Ryan** and J **Lennon**: The condensation of aldehydes with methylethylketone: γ-benzylidene-methylethylketone condenses with benzaldehyde to yield isomethyldiphenylcyclopentenone, with anisaldehyde to yield 1-methyl-4-anisyl-5-phenyl-cyclo-penten(3)-one(2) and with piperonal to form 1-methyl-4-piperonyl-5-phenyl-cyclo-penten(3)-one(2) When isomethyldiphenylcyclopentenone is warmed with dilute alcoholic hydrochloric acid, it changes into methyldiphenylcyclopentenone This compound condensed with benzaldehyde to yield benzylidene-methyldiphenylcyclopentenone, which is identical with the tri-condensation product of benzaldehyde and methylethylketone obtained by Ryan and Devine. Anisaldehyde condensed with methylanisylphenylcyclopentenone to yield anisylidene-methylanisylphenylcyclopentenone, and the isomeric compound obtained by Ryan and Devine by the action of anisaldehyde on α-benzylidene-methylethylketone is anisylidene-methylphenylanisylcyclopentenone.

CALCUTTA

Asiatic Society of Bengal, January 7 —Johan van **Manen**: A collection of Tibetan proverbs. More than 200 sayings have now been gathered —Sunder Lal **Hora**: On the habits of a succineid mollusc from the Western Ghats. In August 1924 a new species of Succinea was discovered hibernating on the bark of mango trees at Lonavla. Several members of the family Succineidæ are known to tide over periods of draught by æstivating, but none have so far been recorded in a comatose condition during the rainy season Other members of this family have been found on rocks, but this is the first occasion when a succineid mollusc has been found hibernating on barks of trees.

SYDNEY.

Linnean Society of New South Wales, November 26. —H. M. **Hale**: Two new Hemiptera from New South Wales. Description of a new genus, from Berowra

Creek and Epping, belonging to the Notonectinæ, and a new species of Salda from Wentworth Falls.—W. A. **Haswell**: Critical notes on the Temnocephaloidea. A description is given of the female part of the reproductive apparatus in various species of Temnocephala from Australia, New Zealand, and South America. The relations of the vesicles variously known as receptacula seminis, receptacula vitelli, and vesiculæ resorbientes are described and their functions and homologies discussed.—P. **Brough**, J. **McLuckie**, and A. H. K. **Petrie**: An ecological study of the flora of Mt. Wilson. Pt. I: The vegetation of the basalt. The origin and distribution in Eastern Australia of the Malayan floristic elements are discussed, and an account is given of the structure, composition, inter-relationships, and distribution of the plant communities occupying the basalt caps at Mt. Wilson, the flora of which is largely composed of Malayan elements. A detailed study is made of the overlapping of the Malayan flora of the basalt, and the endemic flora of the adjacent sandstone.

WASHINGTON, D.C.

National Academy of Sciences (Proc., Vol. 10, No. 11, November).—H. **Fricke** and O. **Glasser**. The secondary electrons produced by hard X-rays in light elements. The ionisation current was measured in ionisation chambers (0·5-9 c.c. in volume) constructed entirely of the material under examination, which are small in comparison with the path of the photo-electrons in the chamber. In these circumstances, the current can be represented, according to Compton's theory of scattering of X-rays, as the sum of two quantities, one of which is independent of the effective atomic number of the scattering substance. The ratio of these quantities is determined and agrees with that calculated, using Compton's theory, from other data, for two nearly homogeneous radiations.—C. **Barus**: The diffusion of hydrogen into air, measured by the interferometer U-gauge. Essentially, the method is to measure the pressure at the closed top end of a vertical tube while hydrogen diffuses from the open bottom end. Using various tubes of different length and diameter, the diffusion constant is always considerably higher than the generally accepted value.—W. N. **Birchby**: White light interference fringes with a thick glass plate in one path. A glass plate is inserted in one of the paths of a Michelson interferometer. The fringes are alternately red and green, while the central fringes are indeterminate. For the central region the effect is due to interference in one narrow range of the spectrum superimposed on uniform illumination from the rest of the spectrum.—J. **Kendall** and J. F. **White**: The separation of isotopes by the ionic migration method. If isotopic ions have significant different mobilities, it should be possible to effect separation by electrolysis (NATURE, June 2, 1923, p. 763). Preliminary short runs were made in which it was found possible to effect separation of iodide and thiocyanate ions (16 per cent. mobility difference), barium and calcium ions (8 per cent. difference), barium and strontium ions (5 per cent. difference), and iodide and chloride (about 1 per cent.). A 5 cm. sodium chloride section (0·1 N) between sodium hydroxide and acetate was moved 1000-2000 cm. with inconclusive results. The tubes used, 1·5 in. wide, are not big enough to give segments suitable for ordinary analysis.—W. J. **Crozier**: On the possibility of identifying chemical processes in living matter. Chemical transformations proceed according to Arrhenius's equation, that the velocity of monomolecular change is proportional to the exponential of $-E/RT$, where R is the gas constant, T the absolute temperature, and E is the amount of heat required to convert 1 gm. molecule of the reactant from an inactive to a reactive form. E is thus characteristic of the reactant and, in simple chemical processes, of the catalyst. The velocities of many biological processes are influenced by temperature in a manner similar to ordinary chemical reactions, and the critical increments, or *temperature characteristics*, of the former fall into definite groups. Physiological transformations of a similar type give identical values for this constant suggesting the presence of similar catalytic agents (*not* enzymes). This points to the possibility of the identification of chemical transformations in undisturbed living matter.—R. L. **Moore**: Concerning sets of segments which cover a point set in the Vitali sense.—A. E. **Kennelly**: Time constants for engineering purposes in simple exponential transient phenomena.

Diary of Societies.

MONDAY, FEBRUARY 2.

CAMBRIDGE PHILOSOPHICAL SOCIETY, at 4.30.

ROYAL INSTITUTION OF GREAT BRITAIN (General Meeting), at 5.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. Z. Cope: Extravasation of Bile.

SOCIETY OF ENGINEERS (at Geological Society), at 5.30.—A. S. Buckle: Presidential Address.

INSTITUTION OF ELECTRICAL ENGINEERS (Western Centre) (at Plymouth), at 6.—H. Marryat: Electric Passenger Lifts.

INSTITUTION OF ELECTRICAL ENGINEERS (Tees-Side Sub-Centre) (at Cleveland Technical Institute, Middlesbrough), at 7.15.—G. Rogers: Automatic and Semi-Automatic Mercury Vapour Rectifier Substations.

JUNIOR INSTITUTION OF ENGINEERS (North-Western Section) (at 16 St. Mary's Parsonage, Manchester), at 7.15.—G. B. Walker: The Design and Construction of a Piano Player.

ARISTOTELIAN SOCIETY (at University of London Club, 21 Gower Street, W.C.), at 8.—Prof. G. H. Langley: Values and Temporal Experience.

ROYAL SOCIETY OF ARTS, at 8.—V. E. Pullen: Radiological Research—a History (III.) (Cantor Lectures).

SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Chemical Society), at 8.—E. J. Lush: Kinetics of Hydrogenation.—C. O. Condrup and E. W. Smith: Tar Distillation by means of the T.I.C. (Lead Bath) Process.

INSTITUTE OF THE RUBBER INDUSTRY (London Section) (at Engineers' Club), at 8.—W. G. Martin: The Calender in the Rubber Industry.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.30.—President's Address and Presentation of Prizes.

TUESDAY, FEBRUARY 3

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Dr. H. R. Hall: The Connexion and Relations of the Prehistoric Greek and Ancient Egyptian Civilisations (II.).

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY, at 5.30.—Prof. W. L. Bragg: (*a*) Model illustrating the Formation of Crystals; (*b*) Exhibit of Diffraction Gratings constructed to illustrate the Effect of Crystals on X Rays.—R. W. James: The Structure of Barium Sulphate.—Dr. E. C. S. Dickson: The Flettner Rotor Sail.

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5.30.—Dr. H. I. Waterman and J. N. J. Perquin: Decomposition of Paraffin Wax at 450° C. in Presence and in Absence of Hydrogen under High Pressure.

ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—Secretary: Report on the Additions to the Society's Menagerie during the months of November and December 1924.—G. C. Robson: Exhibition of a Giant Squid (*Stenoteuthis caroli*) recently stranded on the Yorkshire Coast.—M. S. Mackinlay: The Language of the Emotions.—Universal Methods of Expression.—Dr. N. S. Lucas: Ill-health in Captive Wild Animals and its Causes.—Prof. O. Fuhrmann and Dr. Jean G. Baer: Zoological Results of the Third Tanganyika Expedition conducted by Dr. W. A. Cunnington, F.Z.S., 1904–1905.—Report on the Cestoda.—Doris R. Crofts: The Comparative Morphology of the Cecal Gland (Rectal Gland) of Selachian Fishes.—S. Hirst: Descriptions of New Acari, mainly parasitic on Rodents.

INSTITUTE OF MARINE ENGINEERS, at 6.30.—W. B. Lewis and G. S. Irving: The Treatment of Boiler Feed Water.

INSTITUTION OF ELECTRICAL ENGINEERS (North Western Centre) (at Engineers' Club, Manchester), at 7.—A. B. Mallinson and others: Discussion on Justifiable Small Power Plants.

INSTITUTE OF METALS (Birmingham Section) (at Chamber of Commerce, Birmingham), at 7.—Discussion on Metal Melting.

INSTITUTION OF AUTOMOBILE ENGINEERS (Coventry Section) (at Broadgate Café, Coventry), at 7.15.

SOCIETY OF CHEMICAL INDUSTRY (Birmingham and Midland Section) (at Birmingham University), at 7.15.—Dr. T. Slater Price: The Action of Light on the Photographic Plate.—J. I. Graham and F. Lawrence: The Use of Iodine Pentoxide in the Estimation of Carbon Monoxide.

INSTITUTE OF METALS (North East Coast Section) (at Armstrong College, Newcastle-on-Tyne), at 7.30.

RÖNTGEN SOCIETY (at British Institute of Radiology, 32 Welbeck Street, W.), at 8.15.—Major C. E. S. Phillips: Constant Voltage High Tension Generators.—C. H. Holbeach: (*a*) Some Further Aspects of the Theory and Operation of Potter Bucky Diaphragms; (*b*) Demonstration of the New C.D.X. Dental X-Ray Equipment.

WEDNESDAY, FEBRUARY 4

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. H. P. W. White: The Pathology of Hydronephrosis.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—Dr. A. Heard: The Petrology of the District between Nevm and Clynnog-fawr (Carnarvonshire).

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section), at 6.—L. B. Turner and F. P. Best: The *Optimum Damping* in the Auditive Reception of Wireless Telegraph Signals.

ROYAL MICROSCOPICAL SOCIETY (Biological Section), at 7.30.

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (Annual General Meeting) (at Chemical Society), at 8.—Presidential Address.—(Ordinary Meeting).—Dr. D. Hooper: Cinchonine as a Tannin Precipitant with Special Reference to the Analysis of Cutch and Gambier.—C. Ainsworth Mitchell: The Examination of Charred Documents.—H. R. Ambler: The Absorption of Carbon Monoxide in Gas Analysis.

ROYAL SOCIETY OF ARTS, at 8.—Sir Ernest Rutherford: The Stability of Atoms (Trueman Wood Lecture).

ENTOMOLOGICAL SOCIETY OF LONDON, at 8.

ROYAL SOCIETY OF MEDICINE (Surgery, Medicine, Anæsthetics, Pathology, Obstetrics and Gynæcology Sections), at 8.—Sir Charles Gordon-Watson, E. C. Lindsay, and others. Special Discussion on The Prevention and Treatment of Post-Operative Pulmonary Affections.

THURSDAY, FEBRUARY 5.

ROYAL SOCIETY, at 4.30.—H. M. Carleton. Growth, Phagocytosis and other Phenomena in Tissue Cultures of Fœtal and Adult Lung.—F. W. Fox and J. A. Gardner: The Origin and Destiny of Cholesterol in the Animal Organism. Part XIV. The Cholesterol Metabolism in Normal Breast-fed Infants.—H. H. Thomas: The Caytoniales. A new Group of Angiospermous Plants from the Jurassic Rocks of Yorkshire.—Dr. Winifred Brenchley and H. G. Thornton: The Relation between the Development, Structure, and Functioning of the Nodules on *Vicia Faba* as influenced by the Presence or Absence of Boron in the Nutrient Medium.—*To be read in title only*.—A. S. Rau, F. W. R. Brambell, and Prof. J. B. Gatenby. Observations on the Golgi Bodies in the Living Cell.—V. Nath: Cell Inclusions in the Oogenesis of Scorpions.—L. J. Harris: The Combination of Proteins, Amino-Acids, etc. with Acids and Alkalis and their Combining Weights, as determined by Physico-Chemical Measurements.

LINNEAN SOCIETY OF LONDON, at 5.—Dr. G. P. Bidder: Growth and Death. a Discussion.—Dr. J. Burtt-Davy: The Geographical Distribution of the Arborescent Vegetation of Subtropical South Africa.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Sir William Bragg: The Properties and Structure of Quartz (II.).

ROYAL AERONAUTICAL SOCIETY, at 5.30.—Air Commodore C. R. Samson: The Operation of Flying Boats in the Mediterranean.

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Mrs. V. Plincke: The Waldorf School, Stuttgart.

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—Dr. J. H. Jeans: Electrical Forces and Quanta (Kelvin Lecture).

SOCIETY OF CHEMICAL INDUSTRY (Bristol Section) (at Bristol University), at 7.30.—P. G. J. Guetsebock: Tin.

CHEMICAL SOCIETY, at 8.

SOCIETY OF DYERS AND COLOURISTS (West Riding Section).—Prof. H. E. Armstrong: Colour Problems.

INSTITUTION OF MECHANICAL ENGINEERS (Glasgow Meeting).—J. Biggam: Methods of Determining the Properties of Steam.

INSTITUTION OF MECHANICAL ENGINEERS (Birmingham Meeting).

FRIDAY, FEBRUARY 6

ROYAL SOCIETY OF ARTS (Indian Section), at 4.30.—J. T. Marten: The Indian Census.

ROYAL DUBLIN SOCIETY, at 4.30.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. A. H. Todd: Syphilitic Arthritis.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—J. B. Dahlerus: Anti-Friction Bearing Applications for Heavy Duty.

SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (at 16 St. Mary's Parsonage, Manchester), at 7.—Dr. T. Callan: The Detection and Determination of Alpha-Naphthol in Beta-Naphthol.—W. J. S. Naunton: Some Organic Rubber Vulcanising Accelerators.

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—E. G. Herbert: The Measurement of Hardness and Allied Properties of Metals.

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Middlesbrough Graduate Section) (at Cleveland Scientific and Technical Institution, Middlesbrough), at 7.30.—H. Smith: Constructional Work.

PHILOLOGICAL SOCIETY (at University College), at 8.—N. W. Thomas: The Sudanic Languages.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Prof. R. W. Chambers: The Earliest Recorded Kings of the English.

SATURDAY, FEBRUARY 7

GILBERT WHITE FELLOWSHIP (at 6 Queen Square, W.C.), at 3.—Dr. J. R. Leeson: The Evolution of Man.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Dr. E. H. Fellowes: The Elizabethan Ayre.

PUBLIC LECTURES.

SATURDAY, JANUARY 31.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Miss M. A. Murray: The Empire *of* Egypt.

MONDAY, FEBRUARY 2

LONDON SCHOOL OF ECONOMICS AND POLITICAL SCIENCE, at 5.—Dr. E. B. Behrens: International Labour Organisation.

BIRKBECK COLLEGE, at 5.30.—Dr. G. G. Coulton: Medieval Education (I.). The Monastic School.

TUESDAY, FEBRUARY 3.

MIDDLESEX HOSPITAL MEDICAL SCHOOL, at 5.—E. C. Dodds: Chemistry of the Internal Secretions. (Succeeding Lectures on February 5, 10, 12, 17, 19, 26, and March 3.)

UNIVERSITY COLLEGE, at 5.30.—W. J. Perry: The Beginnings of Civilisation.—W. H. Baynes: Some Aspects of Byzantine Civilisation (I.). Constantinople. (Succeeding Lectures on February 10, 17, 24.)

KING'S COLLEGE, at 5.30.—Miss Hilda D. Oakeley: The Religious Ideas of Plato.

GRESHAM COLLEGE, at 6.—A. E. Hinks: Our Place in the Universe. (Succeeding Lectures on February 4, 5, 6.)

UNIVERSITY OF LEEDS, at 8.—Dr. W. H. Pearsall: Woodlands and Moorlands in Yorkshire.

WEDNESDAY, FEBRUARY 4

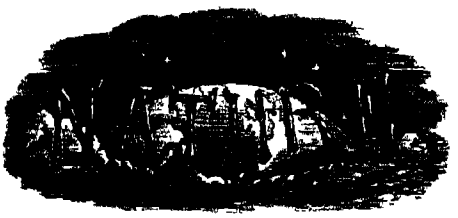
LONDON SCHOOL OF ECONOMICS AND POLITICAL SCIENCE, at 5.—H. P. Shapland: The Principles of Design as applied to Furniture.

KING'S COLLEGE, at 5.30.—Prof. A. Mawer: The Viking Age, A.D. 800-1000.

UNIVERSITY COLLEGE, at 5.30.—R. E. Flower: The Use of Libraries (II.). Collections and Manuscripts.

THURSDAY, FEBRUARY 5.

BIRKBECK COLLEGE, at 5.30.—Prof. E. N. da C. Andrade: The Structure of the Atom (I.). (Succeeding Lectures on February 12, 19.)



KING'S COLLEGE, at 5.30.—Lt.-Commdr. A. S. E. Sutton: The Civilisation of China: General View.

FRIDAY, FEBRUARY 6.

UNIVERSITY OF LEEDS AND LEEDS PHILOSOPHICAL AND LITERARY SOCIETY (at Philosophical Hall, Leeds), at 8.—Prof. J. Garstang: The Archæology of Palestine.

SATURDAY, FEBRUARY 7.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—R. P. G. Denman: The Development of Modern Radio Communication.

SATURDAY, FEBRUARY 7, 1925.

The Future of the British Patent Office.

THE British patent system is a matter which concerns all workers in applied science, for it represents an attempt—faulty and incomplete, but still an attempt—to secure for such workers the credit for their achievements, together with a share of the material advantages arising from these. Hence any event which seriously affects the future of the patent system is one to which the scientific world should give careful consideration, and such an event is just beginning to appear on the horizon. Lest it should take shape before its implications have been seriously canvassed, it may be well to direct attention to some of its aspects. There is a rule which requires Government servants to submit to superannuation at an age when many men are still capable of their best work, and since the rule appears to be inexorably applied, the retirement of the present Comptroller of the Patent Office and the appointment of his successor must be regarded as inevitable in the not very distant future. It is perhaps a little early to discuss this question, but not too early, for when the first official intimation of such a change is given, the selection of the successor may be actually, if not formally, a *fait accompli*.

That a scientific office should have a scientific man at its head is a principle which seems obvious but needs to be constantly reasserted, because the administrative officials who influence such appointments are not always sympathetic towards the claims of science. In fact, a lack of sympathy in that direction is sometimes manifested to a degree which exposes it to strong criticism, as in the proceedings of committees A, B, and C of the National Whitley Council, and in the general tendency to regard the man of science as a mere adviser who is himself incapable of administrative work. Such an attitude is the more unjustifiable from the fact that a scientific training is necessarily always *additional* to some degree of education in the humanities, whereas a literary scholar may be quite ignorant of science; so that the former type of upbringing is the more likely to produce the breadth of outlook which is necessary in handling men and affairs.

Taking the British Patent Office as an example, let us examine the qualifications which are necessary in the man who is to direct its labours. The duties of the Comptroller fall under three heads as follows:

(1) He is the senior Hearing Officer for disputes as to patents, trade marks, and designs. He has to adjudicate in "oppositions" brought by interested parties against the grant of particular patents, as well as in cases where examiner and applicant fail to agree in regard to the official requirements put forward by

the former. Thus the Comptroller is a court of first instance for certain classes of patent litigation; and although he delegates this duty in a proportion of cases to subordinate Hearing Officers drawn from the examining staff, in the remaining cases he acts personally. For the adequate discharge of this function, the importance of which is obvious, the Comptroller should have legal knowledge, experience of patent practice, and such a wide training in scientific matters as to be able readily to appreciate, in the structure and functioning of electrical, mechanical, and chemical systems, those details and subtleties around which patent litigation so frequently turns. Should he lack the latter qualification, the new Comptroller would in many instances be thrown on the mercy of his advisers from the examining staff, and so would relinquish both his dignity and, in the case of disagreement between examiner and applicant, his judicial neutrality.

(2) He will command the staff of the Patent Office, in addition to those of the Trade Marks and Designs Branches The essential work of the Patent Office is carried on by the examining staff, comprising (according to the last Annual Report) more than 250 men having the necessary scientific qualifications, while the routine incidental to their labours necessitates a supplementary staff comprising roughly an equal number of clerical workers. It would be unreasonable to subordinate the examining staff, in the years that lie ahead, to the control of a man who is not qualified, by a scientific training similar to theirs, to understand the outlook and the mentality with which such training is associated. It must be remembered that fundamental changes in the relative importance of the scientific and clerical sections of the staff have followed the changes introduced into the patent system by the Act of 1907.

(3) The new Comptroller will be called upon to advise the government of the day with regard to the improvement and extension of the patent system, which has certain unsatisfactory features, the chief being its incompleteness It is incomplete because the official search is arbitrarily limited to British specifications, because it is imperfectly co-ordinated with other patent systems throughout the British Empire, and because adequate use is not made, for the benefit of national and industrial technology, of the special knowledge acquired by the examining staff (though the latter criticism does not apply to the War period, when many of the staff were drafted to the Ministry of Munitions). In the reconstruction of the Patent Acts the new Comptroller will play a pivotal part, and it is desirable, therefore, that he should have first-hand knowledge of the way in which the present system has worked in practice. Equally must he be a man of broad views and open mind, gifted with that sense of proportion and that *flair* for actualities which characterise the thinking of the quantitative and experimental sciences.

Where, it may be asked, is it possible to find a candidate possessing the necessary legal knowledge, scientific training, experience of patent practice, and largeness of outlook? Three classes of men immediately suggest themselves: (1) The patent bar, (2) the patent agents, and (3) the examining staff of the Patent Office itself. There are difficulties to be encountered in each case. As regards the third group, it is not the general practice of the Treasury to put at the head of a department a man promoted from within it, and we do not know in what circumstances exceptions to this rule are considered feasible. If the Comptrollership should be filled from within the Board of Trade, technical and not purely administrative attainments should decide the appointment. As regards the other two classes, the difficulty is that successful patent barristers and successful patent agents are able to make incomes many times greater than the salary attached to the Comptrollership The dignity of the office might *perhaps* combine with the opportunity of public service which it offers to attract a man of the necessary calibre, but there is a fairer and wiser way to meet the difficulty in question. That way is, to raise the salary of the post to a level commensurate with the importance of the latter

The public interest would suffer if the new Comptroller were to be a man whose lack of the requisite qualifications was only compensated by the possession of influential friends. Particularly would it be undesirable to fill such a post by promotion from the "administrative" or clerical grades of the Civil Service. There is a right place in the scheme of things for the bureaucratic mentality, but that place is not at the head of the Patent Office. While it is true that the business of the State could not be carried on without the meticulous observance of precedent, the mastery of complicated routine, the punctilio of official etiquette which are the special merits of the clerical civil servant, it is equally true that such gifts are not adequate to enlist the confidence of subordinates and of the public on behalf of the chief of a technical office already over-ripe for innovation and development.

Whatever decision may be taken when the time comes, it is earnestly to be hoped that no candidate will even be considered who does not combine with experience of patent practice a thorough training in physical science. It should be an absolutely inviolable principle that an essentially scientific staff should have a man of science at its head.

The Imperial College of Tropical Agriculture.

AT a luncheon at the Mansion House on January 29, given by the Lord Mayor of London and the governing body of the Imperial College of Tropical Agriculture, which is now getting into the swing of its work in Trinidad, Lord Milner's recent appeal for more funds for the endowment of the College was supported by a number of speeches which are of good augury for the future of scientific work in the British tropical colonies.

The Secretary of State for the Colonies (Mr. Amery), in proposing the toast of the College, said that it is an enterprise that holds out great hope in regard to the development of that great imperial asset, the tropical colonies. It is in this light that one should regard it—not as a local affair in Trinidad, but as an Imperial institution, the work of which will have a most important bearing upon the progress of our great tropical Empire This has been much neglected in the past, though it has contributed so much to the wealth of the mother country—through sugar in the West Indies, coffee, coconuts, and tea in India and Ceylon, rubber in Malaya and Ceylon, jute, rice, and many other commodities in India.

From the wetter parts of our tropical possessions we obtain most of our supplies of cacao, cinchona bark for quinine, coconuts and their oil (for soap), copra, coir fibre, coffee, guttapercha, jute (for gunny bags), palm oil (for soap and lubricants), palm fibre (for brushes), rice, rubber, sago, spices, sugar, tea, tapioca, and many fruits, including the banana, and from the drier parts we obtain much tobacco and other products. Tropical Africa now bids fair to go far towards supplying Great Britain with cotton.

Such being the case, one might expect to find much money spent upon the development of the tropical colonies and everything connected with them (especially matters concerned with agriculture and its teaching). In actual fact, their development has largely been effected out of their own revenues, which are in general modest, as they depend mainly upon agriculture. An important departure from this method has recently been made, and the home Government has advanced a large loan to some of the tropical African colonies, with the express object of enabling a rapid development of their systems of transport.

With the great competitive extension of planting and of agriculture generally that is now going on in the tropics, the lack of appreciation of the importance of such an institution as the Imperial College must be due to want of thought. Surely this only needs to be pointed out for some of our wealthy firms and individuals, who have won prosperity from the great industries of rubber, tea, coffee, cotton, coconuts, and other products of the tropics, to come forward with important contributions towards the 100,000*l.* for which Lord Milner has appealed—an endowment to enable the College to make proper use of its great opportunities.

Let it be always remembered that the College is the Imperial College of Tropical Agriculture, and that it is to train men not for Trinidad alone, but for all the widely flung tropical dependencies of the British Empire. It has already received some munificent endowments, but is in need of many more Its land and its largest cash endowment it owes to the Government of Trinidad. It has received machinery to the value of 20,000*l.* from the British Sugar Machinery Manufacturers, and has erected a model sugar factory Messrs. Davidson and Todd, of Port of Spain, have presented the furniture, made of local woods, for the main hall of the College Equipments for rubber, tea, cotton, and others are equally to be desired, and expert staffs are needed to manage them

That important organisations are placing faith in the future value of the College is seen from the fact that the Empire Cotton Growing Corporation, with an executive council composed mainly of Lancashire business men, is sending many of its students to be trained there. These men will have in their hands the chief part in the development of this great industry within the British Empire.

One of the greatest desiderata in the proper opening up of our tropical possessions is a due care for health, and in this connexion it was of great interest to learn from the speech of Sir Arthur Shipley (chairman of the governors) that "the Trustees of the International Health Board (who control the Rockefeller endowments), after careful inquiry into the efficiency and standing of the College, have offered 1000*l.* a year for five years to establish a professorship of tropical sanitation and hygiene", and if this proves a success, Sir Arthur has no doubt that they will continue their benefaction. This still further emphasises the need of the institution for further endowment and equipment.

With the opening of the Imperial College, the older methods of rule of thumb will tend to disappear in the light of modern scientific study, as they have all but disappeared in medicine or surgery. The chance for the young men of to-day, as against their predecessors of thirty years ago, is brighter to an almost incredible degree, provided that men of as good and as capable a type are ready to take advantage of it. Let us wish all prosperity to the Imperial College of Tropical Agriculture under the capable guidance of Dr. Hugh Martin Leake, its new principal, who has lately succeeded to the great pioneer of its fortunes, Sir Francis Watts.

Reminiscences of Great Naturalists.

Impressions of Great Naturalists · Reminiscences of Darwin, Huxley, Balfour, Cope, and others. By Prof. Henry Fairfield Osborn. Pp. xxviii + 216 + 12 plates. (New York and London: Charles Scribner's Sons, 1924.) 12*s.* 6*d* net.

PROF. HENRY FAIRFIELD OSBORN, president of the American Museum of Natural History, distinguished especially for his palæontological researches, was one of Huxley's students and he also worked under Francis Balfour He met Darwin and corresponded with Wallace, he was friendly with the combative Cope and very intimate with Roosevelt So he has given us his impressions of these and others, selecting a dozen out of the fifty-seven 'appreciations" which he has written in the course of his busy life He has indulged his liking for trying to sum people up; and he has cultivated the gift, he tells us, by studies in heredity and racial characteristics and our ancestors of the Old Stone Age For with his studies there has grown the conviction that "our intellectual, moral, and spiritual reactions are extremely ancient, and that they have been built up not in hundreds but in thousands—perhaps hundreds of thousands—of years" This palæontographical line of thought is very suggestive, thus we think of Pasteur as the supreme avatar of the tanners, and of Roosevelt as the glorification of the hunters; but we do not find that Prof. Osborn has allowed it much expression in his book, unless in "the racial soul of John Burroughs."

We suspect that the greater part of the success of Prof Osborn's pictures is due not to any theoretical background, but simply to the fact that he is a large-hearted, open-minded, big-brained naturalist himself, a generous rather than critical painter, who instinctively looks for what is best in his sitters. If we ever rise to having our portrait painted, we shall hope to have it done by Prof Osborn. But they allow you little say in such matters Here, however, is a truly delightful book of impressions, marked by insight, balanced judgment, and humour.

Wallace's portrait must always be difficult, he was so unequal · with a passion for truth-seeking, yet led astray by will-o'-the-wisps; an observer of the highest rank, yet wasting time in trying to prove to fools that the earth is not flat, a serious ponderer over the mysteries of life, yet often far from clear-cut in his thinking—say, over sex-selection or the possible origin of man's musical talents. One of the noblest men we ever met, one of the foundation-layers of modern biology, yet least wise, we think, when he differed most from Darwin. But the immediate point is that Prof. Osborn gives us a beautiful picture of this great servant of the truth.

Osborn was dissecting a lobster in Huxley's laboratory when Darwin came along and gave him a friendly greeting. "He stands much taller than Huxley, has a very ruddy face, with benevolent blue eyes and overhanging eyebrows. . . . My general impression of his face is very pleasant." He had the eyes of "a man who could survey all nature." Perhaps this last sentence gets to the heart of the matter. Darwin's greatest gift was his capacity for unified vision, for seeing things whole He could take in such a comprehensive landscape that the fallacy of partial views was escaped Doggedly, as he says, he gathered his facts until their multitude would have overwhelmed most men, gathered them and gazed at them and tested them, until the ever-lurking generalisation took the form that fitted and made them one. Whoever has come near Darwin in the all-round comprehensiveness of his picture of the struggle for existence, the inter-relations of organisms, or the processes of selection? The reason why he remains, on the whole, so sound is given by Osborn. "His eyes were the eyes of a man who could survey all nature." He speaks also of their "translucent truthfulness," and in his palæontographical vein he refers to the fact that Darwin came of "a long line of compellingly truthful ancestors" As we expected, Osborn gives a robust answer to the question · How stands it with Darwinism to-day? He indicates the developments of Darwinism that are in progress, including, of course, some corrections, but his general view is that Darwinism is going on and going strong We do not, however, agree that Darwin's supreme service was that "he won for man absolute freedom in the study of the laws of nature," for that halo belongs to no single emancipator.

Prof Osborn is at his best in painting Huxley. He brings out his lucidity, his fighting qualities, his loyalty as "Darwin's bull-dog," his powers of brilliant generalisation, his capacity for taking pains, his passion for veracity. Huxley's discernment of affinities has left many a deep mark on zoology. Here were steps of generalising insight of the highest order, and yet "he never contributed a single original or novel idea" to the Darwinian theory. Prof. Osborn regards this as an expression of Huxley's scientific caution—he could not make up his mind to an ætiology (to use his own word); but perhaps it simply meant that his originality and synthetic power found in morphology and taxonomy all the expression that his busy life would allow.

Francis Maitland Balfour was "the most brilliant and lovable of men," "by far the most balanced mind

among all the English biologists"; he set comparative embryology on its feet. But the picture that is given of him is not more than an elusive sketch. There is more body in the contrasted pictures of Joseph Leidy and Edward Drinker Cope, "the very last representatives in America of the older school of naturalists and anatomists, who covered a very broad field." Leidy was essentially a man of peace, Cope a militant palæontologist. Leidy was an exact observer—a Cuvierian; Cope revelled in speculation, with the strands of Lamarck in his intellectual fabric. Leidy was an evolutionist *sub rosa*; Cope radiated evolution from his eyes.

It is very interesting to see how impartially enthusiastic Osborn is in portraying the divergent excellencies of his old friends. His book contains some good stories, and here is one about Cope. A difference of opinion with his friend Persifor Frazer at the American Philosophical Society "led to such a violent controversy that the two scientists retired to the hallway and came to blows! On the following morning I happened to meet Cope and could not help remarking on a blackened eye. 'Osborn,' he said, 'don't look at my eye. If you think my eye is black, you ought to see Frazer this morning!'" We begin to understand better why Osborn insists that we must go back to the Old Stone Age if we are to understand one another. We are glad to be assured, however, that such differences of opinion did not sever the lifelong friendship.

We wish we had left room to speak of the other portraits: of Roosevelt, with his suggestion of tremendous grip—we remember his hand-shake still—and his accurate knowledge of birds and mammals; of James Bryce, keen botanist and geologist, as well as mountain-climber and historian, who died young at eighty-three; of Howard Crosby Butler, the archæological explorer; of John Burroughs and of John Muir (we are ashamed to confess that we never heard of him before), and of Louis Pasteur, who "showed the way to the physical redemption of man, as Newton had opened to us the new heavens and Darwin the new earth." He should stand as "a symbol of the profound and intimate relation which must develop between the study of nature and the religious life of man." Prof. Osborn's portraits are accompanied by very interesting photographs, and the two series throw light on one another. It is one of the most interesting books we have read for some time, provoking reflection, as well as pride and humility. Our only serious criticism is the author's tendency to be too generous. After all, was there a real genius amongst them—we mean a maker of new knowledge that makes all things new? No doubt Charles Darwin discovered a New World, but there were explorers before him as well as before Columbus, and the doctrine of evolution was not created at Down. They were giants these men here portrayed, but, seriously, when we think of it, would we compare any of them intellectually to Newton or Faraday, to Clerk Maxwell or Kelvin? We doubt if biological science has in the past enthralled any minds of the first order of magnitude, except men like Aristotle, Descartes, and Goethe, who could do everything well. So while Osborn asks if we could nurture a mind like Darwin's to-day, and is inclined to answer in a sad negative, our impression is that we may not unreasonably hope to nurture something even better

J. ARTHUR THOMSON.

Modern Views on Cytology.

General Cytology: a Textbook of Cellular Structure and Function for Students of Biology and Medicine. By Robert Chambers, Edwin G. Conklin, Edmund V. Cowdry, Merle H. Jacobs, Ernest E. Just, Margaret R. Lewis, Warren H. Lewis, Frank R. Lillie, Ralph S. Lillie, Clarence E. McClung, Albert P. Mathews, Thomas H. Morgan, Edmund B Wilson. Edited by Edmund V. Cowdry. Pp. vii+754. (Chicago: University of Chicago Press; London: Cambridge University Press, 1924.) 7.50 dollars.

THIS volume—the largest and most comprehensive ever published on the subject of cytology—will stand for many years to come as the most authoritative exposition of a branch of zoology which has grown considerably in recent years It has been written by the foremost cytologists in the United States of America, altogether thirteen workers, eminent in their special branch, having collaborated. The task of editorship was discharged by E. V. Cowdry.

Such a work could not have been written by one man, and it is obvious that no one reviewer can do justice to such a monument of learning. The present reviewer is keenly aware of this, and would have wished, had it been possible, to have had a sectional review, assisted by English cytologists such as Ward Cutler, Agar, Gray, Ruggles Gates, and Heslop Harrison.

Prof. A. P. Mathews in his section discusses "Chemistry and Psychism," and comes to the conclusion that the creation of life is the creation of the "anakinetomeric form," *i.e.* energy-rich type of substance. Prof. Mathews writes:

"It is in fact the luminiferous ether which has made things alive, for ether is the great storehouse of energy; it is itself nothing else than space and time; energy and time. Energy is but ether divided by time. Quantity of energy is quantity of ether per second. So all goes back to the ether; infinity and eternity. From it is derived our energy and life."

It is impossible for a working cytologist adequately to comment on such passages. They may mean something to the metaphysician, but one cannot help feeling that Prof. Mathews' views on the relationship between cell lipins and cell proteins, or on the biochemistry of development, would have been more useful.

The biochemist writing on the subject of the chromosome theory is always interesting. Prof. Mathews plainly, if cautiously, states that it would be difficult for the biochemist to accept the factorial hypothesis on the evidence of chemical analyses of the chromatinic heads of spermatozoa and other nuclei. He points out that it is very improbable that were the chromosomes constituted of widely different genes, they would show so simple and definite a composition.

This is precisely where modern biochemistry fails: it has not kept up with either genetics or descriptive cytology, and probably never will until microchemical methods are more extensively developed The statement made by Prof. Mathews that the spermatid nucleolus disappears during spermateleosis is without doubt incorrect. What happens is that the nucleolar and chromatinic substances come to stain with equal intensity.

M. H. Jacobs contributes a section on the permeability of the cell to diffusing substances: he deals especially with the modern work on intravital staining, and the penetrating powers of various salts and organic compounds. This article should be of the greatest value to cytologists working with *intra vitam* methods, and the part dealing with the subject of dyes, if short, is particularly pertinent: this chapter, as also many others in this book, shows clearly how indeterminate has been a great deal of recent experimental work. The modern zoological experimenter seems able to produce published papers more quickly than any other of his fellow zoologists; such work, carried on without a proper knowledge of the chemical and physical factors involved, is worse than useless. Jacobs' article shows that there is still a great field for examination in cell permeability, but the searcher *must* be properly equipped. Jacobs refers often to the "Donnan equilibrium."

It would be difficult to set proper boundaries to the subject of the reactivity of the cell. Naturally Ralph S. Lillie's section on this subject is somewhat diffuse and deals with much of his well-known work on the transmission of impulses by protoplasm, and especially with the transmission of nerve impulses. As has been remarked with regard to Jacobs' section, this part by Lillie will certainly be of value to cytologists interested in intravital work, and to protozoologists. The basic work on the irritability of plants, such as that of U. Ricca, R. Snow, and H. H. Dixon, is not mentioned.

The editor of the volume, E. V. Cowdry, has written a section on the mitochondria, Golgi apparatus, and chromidial substance. The article is well balanced if a little histological: the contributions of the English workers on the cytoplasmic inclusions in gametogenesis are adequately mentioned, though the whole question of gametogenesis itself is untouched. This can be forgiven in view of the splendid treatment of the pathological side of this important branch of cytology. So much of our meagre knowledge of the function of the cytoplasmic inclusions has been ascertained by studies on gametogenesis, that it seems a pity that Dr. Cowdry did not include a full treatment of the subject. Some of the controversies regarding the inclusions in gametogenesis would surely have been settled had so distinguished a worker as Cowdry seen fit to enter into the field.

The much-abused Golgi apparatus has at last received official recognition. For this the reviewer at least is thankful. Cowdry mentions that the Golgi apparatus does not occur in non-nucleated red blood corpuscles: it occurs in the red blood corpuscles of reptiles and birds, as has recently been shown. With the possible exception of certain Protozoa, the Golgi bodies have been found in all nucleated animal cells at some time in their life-history.

Warren Lewis and Margaret Lewis are so well known for their work in tissue cultures, that one would be led to expect an authoritative account on this subject; nor are we disappointed. This section contains the best photomicrographs of cells published anywhere. Champy's interesting claims with regard to dedifferentiation of cells cultivated *in vitro* are not substantiated by the Lewises.

The most interesting recent discovery with regard to fertilisation is the process as it occurs in the sponge Grantia Here somatic cells are entered, and the spermatozoon swells up and becomes spherical before it is finally carried to the egg. These facts are not mentioned in Lillie and Just's section on fertilisation, nor are the peculiar examples of precocious fertilisation reviewed The entry of the somatic cells in sponges, mammals, and leeches by spermatozoa is not dealt with; this is a pity, because these facts have a very direct bearing on Lillie's fertilisation theory. The more physical side of fertilisation is adequately treated, but the article as a whole suffers from the fact that the authors have not dealt properly with the work of descriptive cytologists such as Jenkinson on the axolotl.

Conklin contributes a suggestive section on cellular differentiation. Some of the continental work on histogenesis, mentioned in NATURE, February 23, 1924, pp. 276-278, has not come up for review, and the physio-

logical aspect is not dealt with; cell-lineage, a branch of cytology inseparably coupled with Conklin's name, is naturally treated exhaustively. To explain the old question of cellular differentiation, Conklin assumes the presence of differential factors of development lying outside the nucleus, such areas being themselves the immediate result of the interaction of the cytoplasm of the nucleus at an earlier stage. Such an assumption certainly explains partly some forms of development, but not all, and the main question is still unanswered.

In the last two chapters we have an account by McClung of the modern aspects of the chromosome theory, and another section by Morgan dealing with his wonderful work on Mendelian heredity. The recent English work on sex-reversal and the so-called suppression of the sex-chromosome is not properly dealt with, and should be included in the next edition.

Some of the sections gain, others suffer, from the personal theories of the authors. On the whole, the bibliographies are as complete as could be desired, and the illustrations are a feature of the work. The book begins with an introduction by E. B. Wilson, the best-known living cytologist, whose work on "The Cell" has been the students' standby for so many years. In a footnote, Prof. Wilson mentions that he is bringing out a new edition of his work. "General Cytology" is a splendid testimony to the high standard of American science, and cytologists on the eastern side of the Atlantic should be full of admiration and properly grateful for such a splendid volume.

J. BRONTË GATENBY.

General Chemistry.

(1) *Introduction to General Chemistry*. By Prof. William Foster. Pp. vii + 643 + 29 plates. (Princeton: Princeton University Press; London: Oxford University Press, 1924.) 17*s*. 6*d*. net.

(2) *A Laboratory Manual in General Chemistry*. By Prof. William Foster. Pp. ix + 205. (Princeton: Princeton University Press; London: Oxford University Press, 1924.) 10*s*. net.

(1) PROF. FOSTER'S volume was printed in an experimental form two years ago and used by nearly 1000 students before being finally revised for publication. It is a very crowded volume, but at the end of each chapter there are references to the sources of the material, which the student is recommended to read for fuller information. It is no small compliment to English authors that the books cited for this purpose are in the great majority of cases the standard works used in Great Britain. This statement applies, not only to the larger text-books, such as those of Roscoe and Schorlemmer, of Mellor and of Friend, the first of which must have provided the materials for scores of smaller works, but still more frequently to the recent single-volume text-books of Lowry and of Partington, which are repeatedly cited in this way.

The chief fault of the book is its extreme compression, which gives the whole volume the appearance of a reprint of a student's notes on lectures, rather than of the lectures themselves; an independent reader would therefore find the book very tiring, but a student already attending a course of lectures could use it with comfort to supplement his own notes, and to recall in a more authoritative form what he had already been taught by word of mouth. The author has, however, been quite lavish in certain directions, notably in supplying 26 full-plate illustrations of distinguished chemists; these are admirably reproduced, and are in marked contrast to the rough line-drawings in the text, and to the printing, which is on paper of such transparency that it is often possible to read words which are printed on the other side of the sheet, with the result that the pages give the impression of being smudged. In two other cases the text is fuller than in the majority of similar books, since statistics of production are given, for example, for steel and copper, where the United States are at the head of the list; and, in connexion with the metallurgy of copper, the author has allowed himself two full-page photographs and a full-page diagram, in addition to two pages of text, to illustrate the smelting and refining of the metal.

The earlier chapters are, as a rule, provided with a summary, and exercises on the chapters are given throughout, culminating in a series of more than 200 problems at the end of the volume. The diligent student may therefore be expected to have acquired considerable skill by the time that he has completed the course, but the book is designed for "high pressure" work, and "low pressure" readers would probably prefer to choose some less strenuous compilation.

(2) Prof. Foster has also compiled a Laboratory Manual, the material for which has been secured during nearly twenty years of actual teaching, and revised from year to year in such a way as to anticipate every possible misunderstanding on the part of the student. The book concludes with an ingenious "preliminary exercise" on the separation of the metals into groups, in the course of which 24 test-tubes of solutions, arranged in alphabetical order, are attacked successively by the familiar group-reagents. The work of compilation has been done well, and the work will be helpful to other teachers who are responsible for practical classes in elementary chemistry.

Our Bookshelf.

Quantitative Organic Micro-analysis. By Prof. Fritz Pregl. Translated from the second revised and enlarged German edition by Dr. Ernest Fyleman. Pp. xv + 190. (London: J. and A. Churchill, 1924.) 12*s.* 6*d.* net.

THE quantitative analysis of minute amounts of organic solids and liquids is an art (or should we say handicraft?) which owes more to Prof. Pregl than to any other worker, and the award of a Nobel prize to him a few years ago was a fitting tribute to his successful services in this field. At present confined almost exclusively to biochemistry (where it will be useful when the elusive vitamin is isolated), organic micro-analysis has an important future before it.

After devoting a chapter to the Kuhlmann balance, a marvellous instrument which weighs to ± 0·001 mgm. at maximum load (20 gm.), the author describes the determination of carbon and hydrogen, nitrogen, the halogens, sulphur, of arsenic, phosphorus, and copper in organic combination, of the carboxyl, methoxyl, ethoxyl, and methyl groups, and adds a chapter on the determination of molecular weight by the boiling-point method. The weight of material required for each analysis is about 12-15 mgm.

The micro-methods have many points of similarity with the older classical methods of Liebig, Dumas, and Carius, and have obviously been developed from these by dint of tremendous patience and devotion to detail, as well as of unusual practical skill. These newer methods demand a very special technique, the acquisition of which would provide a valuable training to the student after—not before—he has mastered the principles and practice of ordinary analysis. Technique is, as a rule, best learnt in the laboratory from a colleague or instructor, not from a text-book; but in the present case the use of a text-book is fully justified, because organic micro-analysis is still very little known in Great Britain, and also because the directions given by Pregl are so detailed, that it is difficult to conceive how any well-trained chemist could fail to learn from them.

One does not, of course, look for literary skill or grace in a work of this kind; and one does not find them. Like most German technical treatises, the style of this work is heavy, and the translator, of set purpose, has not lightened it. As a literal translation the English version is good, but it would have been much better if the German style had been less rigidly reproduced. "Pregl" is an important work, and both publisher and translator deserve our thanks for having made it available to the increasing number of chemists who either cannot read German, or cannot read it with ease or pleasure.

The Heavens. By J. H. Fabre. Translated by Dr. E. E. Fournier d'Albe. Pp. xvi + 336 + 16 plates. (London: T. Fisher Unwin, Ltd., 1924.) 15*s.* net.

FOR lucidity of style, for simplicity of language, and for felicity in illustration, this book on descriptive astronomy is probably unique. Many passages are quite poetical, as, for example, that (pp. 90, 91) on morning, noon, and night, while the charm of others, such as the concluding paragraphs of the lesson on hour and longitude, lies in their wealth of descriptive allusions. Even the elementary mechanics becomes absorbing when clothed in such vivid language, and the explanation of how the earth is weighed, and of such subjects as parallax, inertia, and centrifugal force, are presented in a most attractive style.

The work is divided into twenty-five lessons, or chapters, and of these all, except three, are concerned with the solar system, and principally with an elementary presentation of its mechanics. There is a preliminary lesson on simple geometry, and by the employment of these "modest geometrical studies" the earth is surveyed, and is weighed, the Cavendish experiment being very clearly explained. It is then girdled with circles of latitude, and with meridians of longitude, its rotation is made clear, and the effects of the illumination of the atmosphere and of the refraction of light are applied. There is also a very good chapter on the calendar. These are specimens of the topics dealt with, and there are also chapters on the sun, the moon, the planets, the comets, the fixed stars, and the nebulæ.

The translation is very well done, and there are several notes by the translator to bring the matter in the text up-to-date. But we think that it would have been an advantage had the translator also edited out-of-date statements in the text, as, for example, that Uranus has eight satellites, that the best method of determining solar parallax is by the transit of Venus, as also the distances in light-years given for some of the stars, which are founded on antiquated data. The name Herschel is always wrongly spelt. There are other obvious slips, probably due to faulty proof-reading.

A. L. C.

British Antarctic ("Terra Nova") Expedition, 1910. Natural History Report. Zoology, vol. 8, No. 1: *Crustacea.* Part 8: *Euphausiacea.* By Prof. W. M. Tattersall. Pp. 36 + 2 plates. (London: British Museum (Natural History), 1924.) 5*s.*

THERE are very few groups of invertebrate animals of which it can be said with any probability that nearly all the existing species have now been discovered. This claim was made some years ago by Dr. H. J. Hansen as a result of his extensive studies on the Crustacea of the order Euphausiacea. It is supported by the fact that, in the report on the very large collections of this group made by the *Terra Nova* expedition, Prof. Tattersall has not found it necessary to describe a single new species. He discusses the characters and synonymy of a number of the species and describes a series of the larval stages of *Euphausia longirostris*, which is shown to differ from some of its congeners in having a prolonged larval life and in reaching an unusually large size before assuming the adult form. A considerable part of the memoir is devoted to discussing the distribution of the species obtained in the three areas chiefly explored, the Atlantic, the New Zealand region, and the Antarctic and Subantarctic zones south of New Zealand.

It is pointed out that nearly all the specimens were taken in the surface waters at night. During the daytime very few euphausians were taken, and these were, for the most part, larvæ. While a daily vertical migration to and from the deeper strata of the ocean

has been definitely shown to occur for some species, and is probably characteristic of the epiplanktonic species in general, this explanation does not apply to all cases. In coastal waters, euphausians are sometimes observed at the surface in daylight, and their absence from the tow-net catches may be due to their being able to see and avoid the slowly moving tow-nets. The "full speed" nets used on the *Terra Nova* do not seem to have been efficient for the capture of such comparatively large organisms.

Les Insectes parasites de l'homme et des animaux domestiques. Par E. Séguy. (Encyclopédie pratique du Naturaliste, tome 18.) Pp. 442. (Paris: Paul Lechevalier, 1924.) 30 francs.

FRANCE has produced many notable parasitologists, and Brumpt, Neveu-Lemaire, Blanchard, and Ralliet are familiar names of authors of text-books on their subject. M. Séguy is chiefly known as a dipterist, and his studies on mosquitoes have evidently led him to embrace the wider field of parasitology. Although only five orders of insects directly affect man or his domestic animals, a vast literature has grown around them, and the task of treating them at all adequately from the aspect of parasitology is an unusually heavy one. The handbook of M. Séguy is notable as a very concise and practical illustrated epitome of the subject. He has succeeded in compressing within its small compass a really large amount of accurate information.

The Diptera, being the largest order the parasitologist has to contend with, naturally comes in for the major share of treatment. In dealing with this group, the author adopts the heterodox classification of Lameere, who divides the order into only Nemocera and Brachycera. The latter sub-order is made to include the Nemocera Anomala of Osten Sacken, the Brachycera and all the Cyclorrhapha of the more usual systems. This feature renders the section devoted to Diptera rather difficult to follow until one's previous ideas have been readjusted accordingly. The Mallophaga, Anopleura, and Aphaniptera are also adequately dealt with, but among the Hemiptera the Reduviidæ are perhaps dismissed rather too summarily. The book concludes with a well-chosen bibliography of more than 300 references, which, along with the numerous footnotes, includes most of the important sources of information. A. D. I.

The Romance of the Apothecaries' Garden at Chelsea. By Dr. F. Dawtrey Drewitt. Second edition. Pp. 136+15 plates. (London and Sydney: Chapman and Dodd, Ltd., 1924.) 5*s.* net.

How many persons pass daily by the modest botanical garden in Swan Walk, Chelsea, in blissful ignorance of its origin, its antiquity, and the romance attached to it. Dr. Drewitt's charming little work would tell them that it was established about 1673 by the Society of Apothecaries in order that their apprentices might make themselves familiar with the plants used in medicine that, later on, they would be prescribing for their patients. It would give them an insight into the separation of the Apothecaries from the Grocers, of the opposition the new Company had to face, the vicissitudes through which it had to pass, and the sacrifices it had to make to maintain its garden. Dr. Drewitt has understood how to weave into his account much of the changes that London and the surrounding villages have undergone during the last three centuries. He tells us of Johnson, Miller, Sir Hans Sloane, Sir Joseph Banks, and other celebrated men who did so much for the Garden, which attained so high a reputation that, as a letter written by a friend of Linnæus to Miller when curator clearly shows, it was the Apothecaries' Garden which brought Linnæus to London. The second edition of the book contains many additional details concerning the history of the trees in the Garden, so that even any one accustomed to use it for the purposes of study will take a far greater and more intelligent interest in it. The book is most fascinating, and can be read again and again with pleasure and profit.

The Kinetic Theory of Gases. By Prof. Eugène Bloch. Translated by P. A. Smith. Pp. xiv+178. (London: Methuen and Co., Ltd., 1924.) 7*s.* net.

THIS translation, which is taken from Prof. Bloch's work, dated 1921, should meet with a welcome from English readers. The work contains a large amount of information on subjects which commonly find no place in the average text-book. Recent investigations have made the kinetic theory of fluids one of the most vital branches of theoretical physics. Experimental progress has gone hand in hand with the development of theory. There are interesting chapters on statistical mechanics, the theory of quanta, and the Brownian movement and fluctuations. At first sight the width of spectrum lines scarcely seems related to the subject of the book, but the author shows clearly how the width depends on the collisions of the molecules and on their thermal motions. The translator, who has done his work in a very satisfactory manner, has prepared a more complete bibliography of recent papers dealing with the subjects discussed in the various chapters of the book.

Hellenistic Philosophies. By P. E More. (The Greek Tradition from the Death of Socrates to the Council of Chalcedon, 399 B.C. to A.D. 451, Vol. 2.) Pp. v+385. (Princeton: Princeton University Press; London: Oxford University Press, 1923.) 13*s.* 6*d.* net.

THIS is the second volume (the first dealt with the religion of Plato) of a notable comprehensive account of the Greek philosophical tradition. In Mr. More's view, it ends in scepticism, but arises to new life in Christianity. Two other volumes carrying on the tradition are promised. Mr. More writes with ease and distinction and the book is beautifully printed. The absence of an index seriously handicaps it as a book of reference.

Practical Organic Chemistry. By Prof. Julius B. Cohen. Third edition. Pp. xv+520. (London: Macmillan and Co., Ltd., 1924.) 6*s.* 6*d.*

STUDENTS of organic chemistry are indebted to Prof. Cohen for a series of excellent text-books, and this revised edition of his "Practical Organic Chemistry" reaches a high standard. It covers a wide field, including biochemical preparations, and references to the literature are given. A good feature is the very instructive collection of explanatory notes. The book may be recommended as by far the best in any language, and the price is most reasonable.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Origin of Sponge-Spicules.

To account for the extraordinarily beautiful and varied forms of sponge-spicules, with their wonderful symmetry, has long been one of the most puzzling problems of the zoologist After more years of investigation than I care to number, I have arrived at certain conclusions that may interest the readers of NATURE It is, however, a long story, of which I cannot here give more than the barest outline, to be followed, I hope, by a fuller account in another place. For the sake of brevity I must also confine my remarks almost exclusively to siliceous spicules

The generally accepted idea that these spicules arise in "mother-cells" must be abandoned, the so-called mother-cells being, in fact, cells which have enveloped the growing spicule secondarily, after the fashion of phagocytes Their function is either, as silicoblasts, to deposit silica upon the spicules, or, as simple amœbocytes, to carry them from place to place The primary axis around which the silica is deposited is the protorhabd (axial thread), represented in old and eroded spicules by the axial canal. The origin of the protorhabd has hitherto been a complete mystery I believe that it begins as a very minute granule, resembling a micrococcus, capable of movement from place to place, of multiplication by fission, and of growth by elongation and sometimes branching. Regarded as quasi-independent organisms, living symbotically with the sponge, these granules may be termed sclerococci; looked on simply as spicule initiators, they may be termed scleroplastids. Around the usually much elongated scleroplastids, or protorhabds, concentric layers of silica are deposited by silicoblasts, which associate themselves temporarily with the spicules for this purpose, and may exercise a mechanical influence upon their form

The number and arrangement of the rays of the spicule depend upon the number of divisions of the original scleroplastid and the positions which the products of these divisions take up. In the tetract spicule, for example, the original scleroplastid divides into four, which arrange themselves in the form of a pyramid and then elongate centrifugally Secondary growing points may be established by other scleroplastids settling down upon the young spicule and forming new centres of silica deposition.

The evidence on which these conclusions are based can only be summarised in the briefest manner.

(1) In *Stelletta hæckeli* we find many abnormal tetracts (triænes) with more or less suppressed rays, forming a well-graduated reduction series, the protorhabds (still indicated by the axial threads), having been checked in their growth and completely enveloped in silica at various stages of elongation (Fig. 1, 1-5). This reduction series culminates in a perfect sphere of concentrically laminated silica (Fig 1, 6), with a minute granule, representing the original scleroplastid, in the centre. Such spheres are not infrequently met with in siliceous sponges and have been called "siliceous pearls."

(2) Abnormal spicules are often found with adventitious rays developed in unusual situations, and sometimes distinguishable as shafts and cladi. These are to be explained on the hypothesis that wandering scleroplastids settle haphazard on the young spicule and there initiate each its own special kind of ray. In Schmidt's *Stelletta pathologica* nearly all the larger spicules are quite abnormal, formed of rays that have come together apparently by chance, like the members of an Empedoclean monster.

(3) The amphitriæne, which occurs rarely, and usually, if not always, as an abnormality, is readily explicable as a case of incomplete twinning due to abnormal but symmetrical divisions of the original scleroplastid.

(4) I suggested some years ago that in certain spicules with whorled outgrowths the whorls are initiated by groups of "formative" or "initial cells," which settle on the nodes of a vibrating rod, a conclusion which was mathematically supported in a very striking manner by Prof. J. W. Nicholson. These so-called initial cells are really very minute growing points, in each of which a scleroplastid probably forms a centre of attraction for the silica. In the anisodiscorhabds of *Latrunculia bocagei* there are normally two tripartite whorls, each with three growing points. Cases of complete twinning sometimes occur, in which two such spicules, of greatly reduced size, develop

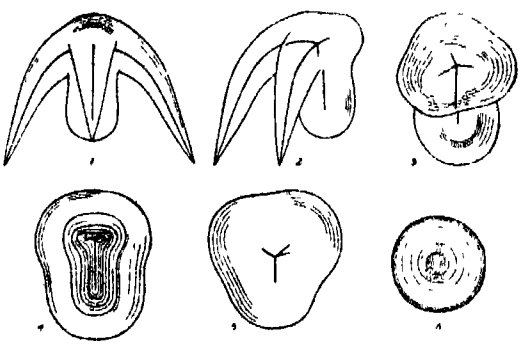

FIG. 1.—Suppressed tetract spicules (triænes) of *Stelletta hæckeli*. × 140.

side by side, but each of these twins has only one whorl. This indicates very clearly that the scleroplastids initiating the two whorls have undergone the usual number of divisions but that their products have distributed themselves over two spicules instead of one.

This last observation seems to me conclusive as to the existence of the scleroplastids as mobile and dividing granules of extremely minute size. The evidence that these are symbiotic organisms (sclerococci) is admittedly less convincing, but seems to me fairly strong.

(1) It is well known that along various lines of phylogenetic descent entire spicule categories mysteriously drop out. Thus we have Stellettids that have lost their triænes, Desmacidonids that have lost their chelæ, and so on. In Chondrilla all the megascleres have disappeared, and in Chondrosia there are no spicules left at all. I was formerly inclined to attribute this loss to the dropping out of Mendelian factors. It may be more simply explained as being due to non-infection by sclerococci

(2) Various cases of the abnormal occurrence of particular types of spicule may be explained by abnormal infection.

(3) In the Euceratosa, with the exception of Darwinella, there are never any spicules at all. Darwinella, however, has, in addition to the normal horny skeleton, radiate spicules composed of spongin, presumably deposited around protorhabds.

(4) In many species of Mycale and Esperiopsis three types of chelæ occur. This may be interpreted to mean that the sclerococci sometimes conjugate and occasionally hybridise, so that we get the two parent

forms of chela and a hybrid. But more evidence is required before this view can be definitely established.

It is difficult to regard the scleroplastids (sclerococci) as genuine constituents of the sponge. They are not nucleated cells but seem to resemble Bacteria in many respects, and I suggest that they are handed on from generation to generation of sponges by egg-infection The sponge converts many of these symbionts into spicules (siliceous, calcareous, or horny as the case may be), and then makes use of the larger ones by building them up into a more or less regular skeleton. The smaller ones it usually makes no use of at all, but either removes them by means of phagocytes or leaves them scattered irregularly through the soft tissues It may be suggested that it is a case of parasitism rather than symbiosis, but evidently the sclerococci are not all destroyed by the sponge, and both parties probably benefit by the association

Experimental investigations by means of inoculation and so forth remain to be attempted, and I hope that this communication may serve to direct attention to a new and promising field of research. The fact that naked sclerococci have not yet been recognised may very well be due to the difficulty of distinguishing them from ordinary Bacteria and from other minute granules with which the tissues of sponges abound ARTHUR DENDY.

King's College, London,
January.

On the Excitation of Spark Spectra.

THE great number of unsuccessful attempts to observe a spark spectrum of lithium have proved the difficulty of exciting, by means of the ordinary methods, the spark spectrum of an element when the excitation potential is high compared with that of the arc spectrum of the same element. Owing to the great interest which is attached not only to the lithium spark spectrum, but also to many other spark spectra which have hitherto not been observed, experiments have been carried on at this Institute during the last two years with the purpose of developing a method which should make it possible to produce spark spectra having a high value of the excitation potential. An apparatus was designed, in which the vapour of the element under investigation was allowed to escape into a high vacuum from a little hole in a crucible, heated by an electric furnace, and where this vapour could be exposed to a bombardment by a strong current of electrons. By evacuating the apparatus to a pressure below 0·001 mm., and by means of a special design of the orifice of the crucible, it was possible to produce and accelerate these electrons, before they could collide with the atoms of the escaping vapour. In the latest construction of the apparatus, the distance from the tungsten filament to the grid was 1-2 mm., the distance from grid to the crucible 10-15 mm., and the electron current was, by means of an anode behind the crucible and a ring near the grid, concentrated on the hole of the crucible where the concentration of vapour was a maximum. The electron current was usually of the order of 200-300 ma, but could without difficulty reach more than 500 ma. Accelerating voltages up to 1400 volts have been applied.

In the first experiments the crucible was filled with easily evaporated metals like sodium, potassium, cadmium, and zinc, and promising results were obtained. Besides the arc spectrum, which was always fully developed with high members of the series, the spark spectra of these elements were observed with considerable intensity at low accelerating potentials of a few hundred volts. Also, with salts in the crucible, spark spectra were in various cases obtained without difficulty.

Owing to the very high boiling-point of metallic lithium and the small dissociation of its salts, it was not found possible in the first apparatus, where the crucible could not be heated above 600°, with this element to produce a sufficient high vapour pressure. With a redesigned apparatus, in which the crucible could be heated to 1000° C., we succeeded, however, in obtaining several lines of the lithium spark spectrum which appeared with considerable intensity with an accelerating voltage of about 300 volts.

While this second apparatus was under construction, Schüler in a recent note (*Die Naturwissenschaften*, July 11, 1924) communicated various important results regarding the lithium spark spectrum, obtained by the beautiful method of the hollow cathode, developed by Paschen. In addition to the line 2934 Å.U., ascribed to lithium by Mohler (*Phys. Rev.*, 23, 108, 1924), Schüler observed a number of new lines which made possible the establishment of the main features of a series scheme with fourfold Rydberg constant, which therefore was ascribed to the singly ionised lithium atom In accordance with the theoretical expectation, that this spectrum should show a great similarity with the ordinary helium spectrum, it was also found possible in the spectrum to recognise two separate series systems At the same time, observations of a number of lines ascribed to the lithium spark spectrum were recorded by M. Morand (*C R*, May 1924) The method of excitation used in his work was that of anode rays While in our experiments only few of the lines given by Morand could be verified, most of Schuler's results were confirmed, although it seemed necessary to introduce small corrections in some of his wave-lengths, and a few modifications in the series scheme proposed The results are stated in the following table, where the wave-lengths are given with an average accuracy of about 0 4 Å.U. The numbers in brackets are the estimated intensities.

3285·8	(1)	3*S*-4*P* ?	2728 9	(1)	3*d*-6*f*
			2612	(½)	3*P*-6*D* ?

Following Schüler, a term notation analogous to that of the helium spectrum is used, the terms denoted by small letters being assumed to correspond with the helium terms of the doublet series, while the terms denoted by capital letters are assumed to correspond with the helium singlet system While most of the lines were rather faint compared with the arc-lines, the line 5485 5 was comparatively bright, and appeared, when observed visually, with about the same intensity as the red and yellow lines of the lithium arc spectrum. This line was originally ascribed by Schüler to the presumed singlet spectrum, but from a more recent observation, kindly communicated to this Institute by Prof. Paschen, that the line in question when observed with high dispersion exhibits a complex structure, Schuler has later concluded that it must belong to the doublet spectrum. This conclusion is also in conformity with our measurements. Not only does it seem impossible in any other way to account for its intensity relative to the other observed lines, but also the absolute value of the wave-length is in complete agreement

with what should be expected from the series relation given in Table I. In fact, this leads to the following scheme of the terms of the doublet spectrum.

TABLE II.

$2s = 134,056$	$(n^* = 1{\cdot}81)$	$2p = 115,831$	$(n^* = 1{\cdot}95)$	$3d = 48,828$	$(n^* = 3{\cdot}00)$	$4f = 27,430$	$(n^* = 4{\cdot}00)$
$3s = 55,308$	$(n^* = 2{\cdot}82)$	$3p = 50,566$	$(n^* = 2{\cdot}95)$	$4d = 27,455$	$(n^* = 4{\cdot}00)$	$5f = 17,552$	$(n^* = 5{\cdot}00)$
$4s = 30,086$	$(n^* = 3{\cdot}82)$	$4p = 28,180$	$(n^* = 3{\cdot}95)$	$5d = 17,569$	$(n^* = 5{\cdot}00)$	$6f = 12,193$	$(n^* = 6{\cdot}00)$
$5s = 18,883$	$(n^* = 4{\cdot}82)$	...		...		...	

The numbers in the brackets are the effective quantum numbers of the various terms. It will be seen that these numbers exhibit a great similarity with those of the helium-doublet spectrum, although the differences from the corresponding hydrogen values are slightly smaller in the case of the lithium spark spectrum, as should also be expected from general theoretical considerations. On account of the smaller number of the observed singlet terms and the great uncertainty attached to their series arrangement, we have confined ourselves to giving in Table I. a preliminary series notation

In addition to the spark spectrum of lithium, the arc spectrum (lithium I-spectrum) was very strongly excited. The sharp and the diffuse series were observed up to the 10th and the 14th member, respectively

No attempt was made to determine the minimum excitation potentials of the spark spectrum lines, but it was observed that between 150 and 200 volts accelerating potential, the intensity of the line 5485 Å.U. decreased very rapidly relative to the arc lines. An increase of accelerating potential from 300 volts to 1000 volts had no effect on the relative intensity of the arc and spark spectrum.

In addition to this method of excitation by means of impacting electrons, the lithium spark lines were also obtained under somewhat different conditions. If the vapour pressure was high and the potential between the crucible and the anode was more than 500 volts, then under the electron bombardment an arc would strike between the crucible and anode, and this arc would continue even after the electron current was cut off. This arc, in which the potential drop was 400-500 volts, and the current 400-500 ma, showed a brilliant luminescence and exhibited besides the ordinary arc lines also the spark lines, especially the line 5485 Å.U., with considerable intensity. However, excited in this way, the relative intensity of the spark spectrum compared with the arc spectrum is much smaller than when the spectra were excited by means of electron bombardment. The work will be continued.

The writer wishes to express his thanks to Dr J. A Christiansen, in collaboration with whom the first apparatus was designed, but who was prevented from taking part in the further developing of the work.

Rainfall Correlations in Trinidad.

AN important feature of modern economic geography is the study of the relationship between climatic conditions and industry. Regarding climate and weather as being respectively the static and dynamic aspects of meteorological conditions, we have in the tropics, as Dr. Martin Leake has recently emphasised, climate a determinate factor in the location of industries and colonies of people; weather, on the other hand, is frequently the most important factor underlying local industrial *variation*. In the tropics, rainfall is generally the chief weather factor affecting crop yields, and in Trinidad (West Indies) the writer has given some attention to the relationship between variation in rainfall and yield of cacao—the island's principal product. This work has definitely established the fact that the annual variations in yield, which may deviate as much as −101·8 per cent. of a 5-year moving average (River Estate, 1921–22), are fundamentally due to variations in rainfall, though the exact extent of the connexion has not been statistically determined in all cases.

The procedure followed in the investigation was to obtain monthly rainfall and monthly crop-yield records for as many years back as possible (generally not more than 15) from the most reliable individual estates, and to work on the data for each estate separately. Finally, the annual output of cacao for the whole island was considered in relation to the average annual rainfall for all cacao districts. On the whole, I am satisfied that the data obtained are sufficiently trustworthy for the purpose of affording general indications.

It will be well to emphasise, however, that studies like the present one cannot be regarded as purely statistical. we are dealing, not with the rainfall itself but with its ultimate effects, and it is necessary to have at least an elementary knowledge of the physiological nature and habits of the cacao tree (in this particular study) in order to anticipate lags and to deal intelligently in general with the data. There is also the question of increasing or declining output as affected by agricultural management. The latter difficulty is partly overcome by plotting the yield deviations from moving averages for, say, 5-year periods. In general the "dot chart" method of plotting yield against rainfall to indicate linear correlation was employed, and in cases where the points clustered adequately, the coefficient of correlation was computed. In all cases the percentage deviations from the averages were plotted as well, in order to compare the magnitude of the variations on the same scale. It is not possible in this short note to reproduce the graphs and all the computations, but they are available for reference. The following table gives the general conclusions arrived at:

Estate.	Geographical location.	Av. ann. rainfall in. (approx.)	Correlation: Yield and rain of "wet" months.	Correlation: Yield and Nov. rain.
La Vega	Central Range	84	Negative	None
Non Pareil	East end of N. Range	95	Negative	Positive
Verdant Vale	Central N Range	85	Negative	Positive
River	West end of N. Range	67	(Inconclusive)	(Inconclusive)
All cacao Districts	North, Central and S.E.	73 (weighted)	Positive within limits	(Undetermined)

It would appear that estates with an average annual rainfall of 80 inches and more are less adapted for cacao, other things being equal, than estates with an average annual rainfall lying between 70 and 75 inches. In the case of La Vega estate the negative correlation was found to be extremely definite, the highest and most remarkable coefficient being in respect of the May and June rainfall and the subsequent crop. This was found to be $-0{\cdot}95 \pm 0{\cdot}10$. It is necessary to mention that this computation was made under my direction but that I have not verified it. For the rainfalls of May only, however, and subsequent yields, I myself obtained a coefficient of $-0{\cdot}85 \pm 0{\cdot}15$, which is equally, if not more surprising, because it refers to one month of the year only, and that six months prior to the coming in of the crop affected.

Verdant Vale estate has a coefficient for November rain of 0·65±0·05. The apparent importance of adequate rain during November in the Northern Range of hills is interesting, and this and many other points require further study.

Generally speaking, rainfall seems to be a fundamental factor underlying the whole economic activity of Trinidad. A close connexion was found by the writer between rainfall in Port of Spain and the electric tram-car takings, and between the business done in the shops The latter is partly due to synchronic weather changes, and partly the effect of the previous year's rainfall and crop yields affecting the purchasing power of the inhabitants.

On the principal rubber estate I found the well-known connexion between daily rainfall and the quantity of rubber tapped from the trees The connexion here is due to purely physical reasons, rain causing the latex to flow over the bark instead of down the central channel into the cup. The influence of rainfall on sugar-cane and coconut yields was not studied, but it may be of interest to mention that considerable work on the former relationship has been done in other countries. The most important, perhaps, of this work is A. Walter's analysis of climatic factors and the cane crop in Mauritius, that of M. Kœnig in the same Colony, and the work of T. A. Tengwall and C. E. van de Zyl in Java, which has recently established a positive correlation between sugar yield per bouw and amount of rain in October and November. A very good summary of the results obtained in the United States in regard to weather factors and cotton, Indian corn (maize) and tobacco, is to be found in J. W. Smith's "Agricultural Meteorology." Most of the correlations obtained in connexion with rainfall and tropical and sub-tropical crops have been in the neighbourhood of 0·60 with probable errors indicating a fair degree of significance.

In conclusion, I should like to emphasise the importance of this work not only from the point of view of physiology and agriculture, but also from the wider point of view of economic geography. Conditions in tropical countries have, for the most part, been fully described, what is needed now is statistical analysis and co-ordination, and from a broad administrative point of view. In Trinidad the general complaint is that short cacao crops are due to drought. On many of the best and largest estates my work indicates that the trouble is the result—or partly the result—of too much rain. W. R. DUNLOP.

Astrophysics without Mathematics.

SIR JOSEPH HOOKER in 1869, in undertaking to review a book for a journal of science, made the following remark: "I hope that . . . will give us better analyses of books than reviews in general afford us. We have no end of reviews, but they are generally the author's views on the subject of the book to be reviewed and convey no precise information as to the books themselves. This is a crying evil." The review by "E. A. M." in NATURE of January 10 of my book, "Modern Astrophysics," is a particularly good specimen of the type of review to which Hooker very properly took exception. The reader of this review who has not seen the book will have not the remotest idea of what I have tried to do, or of the intended (E. A. M. calls the book "amorphous") structure of the book as revealed, say, by the titles of its sections and chapters. Instead of this relevant and, one would have thought, indispensable matter, he is treated to a catalogue of E. A. M.'s misapprehensions of the subject and of his differences from me in matters of opinion.

The book is condemned from the literary point of view; it is implied that it is difficult to comprehend; and a large number of "omissions" and "errors" are selected as examples of "looseness" of reasoning. With regard to the first two points, E. A M 's remarks, when examined, condemn themselves, and need no comment. He is entitled to his opinion, which he is unfortunate enough not to share with a single one of the critics whose qualifications to review the book are of a literary character. I wish only to remark that E A. M. has either not read or forgotten the preface to the book, and that his statement that the reader "is conducted twice round the whole existing observational material" is untrue.

The main part of the "review" is occupied with criticisms of points of detail E A M. has evidently been peering into the book in order to make a collection of all the trivial points to which he can object, and as a result he puts forward eleven points of this kind. The reader of the "review" will probably be surprised to learn that the whole of the material in the book dealing with all except one of the points criticised by E. A. M., when put together, would make up almost exactly one page The material dealing with the remaining point occupies four and a half pages The book contains about 475 pages

It is clearly an abuse of a reviewer's authority to concentrate on points of this kind, even if his criticisms on those points are valid. E A. M., however, has not even that excuse. The only criticism in which I admit he is justified is that I have omitted to describe the general method of determining cluster parallaxes. For pointing out that omission I am indebted to him. On the other matters I have written to him personally, pointing out where he has blundered If, after reading my letter, he so wishes, I am quite prepared to discuss any or all of the points with him when, where, and in whatever reasonable manner he may choose, in public or in private. Considering the tone in which his "review" is written, it is incumbent upon him to accept this offer or to withdraw his remarks at once.

It is very unpleasant to have to reply to a review, but the misrepresentation and tone of E A. M 's essay leave me no alternative in the interests of the truth I have tried to present in my book

HERBERT DINGLE.

Imperial College of Science and Technology,
January 15, 1925.

I AM sorry that my review has caused Prof Dingle so much pain; and I must beg him to accept my assurance that purely scientific considerations were in my mind. My review contains evidence that there were portions of the book which I read with pleasure, and I take this occasion to say so explicitly. I cannot see that my criticisms were outside the province of a reviewer, but I deeply regret that they should have been expressed in language which Prof. Dingle finds discourteous.

With regard to the substance of my criticisms in the main part of the review, I should not have made them unless I were fully prepared to justify them. After carefully examining the arguments brought forward by Prof. Dingle in his personal letter to me, I am unable to withdraw any of the ten points to which he objects, but I am willingly availing myself of the opportunity of discussing them with him privately. I am unable to agree with Prof. Dingle that the points raised are trivial. They all seemed to me either to be of fundamental importance in themselves or to involve fundamental principles.

Trinity College, Cambridge.

The Structure of the so-called Ultraviolet Bands of Water Vapour.

THE so-called ultraviolet bands of water vapour, which must probably be attributed to the OH-molecule,[1] have been the object of an extensive study. Heurlinger[2] succeeded in arranging almost all the lines of the band λ 3064 into 12 branches which he called P_1^k, Q_1^k, R_1^k, P_2^k, Q_2^k, R_2^k ($k = 1, 2$). But it was not possible to give a theoretical interpretation of the bands, and to decide to which quantum states of the molecule the lines belong.[3] Recently, Watson[4] measured the band λ 2811 and showed that it has exactly the same structure as the band λ 3064. These measurements, combined with those of Grebe and Holtz of the band λ 3064, enable us to get a complete insight into the structure of these bands. With the aid of the combination principle it is possible to get the relative values of the rotational terms without any theoretical assumption about the structure of the molecule. The results obtained are summarised below. (Details will be published in the Proc. Roy. Acad. Amsterdam.)

(1) The six branches P_i^1, Q_i^1, R_i^1 ($i = 1, 2$) form one band which we shall denote by I, and the branches P_i^2, Q_i^2, R_i^2 another band (II), so that what is called a band consists in reality of two bands, which must be attributed to different oscillation transitions; *e.g.*

	I	II
λ 3064	0 → 0	1 → 1
λ 2811	1 → 0	2 → 1

(the transition 0 → 0 for λ 3064 I is chosen arbitrarily). Then λ 2811 I and λ 3064 II must have the same initial state, which is confirmed by the combination principle. That the bands λ 3064 and λ 2811 have the same final state was already pointed out by Watson.

(2) The six branches of one band must be represented by the following scheme.

$$\begin{array}{ll} P_1(m) = F_1(m-1) - f_1(m) & P_2(m) = F_2(m-1) - f_2(m) \\ Q_1(m) = F_1(m) - f_1'(m) & Q_2(m) = F_2(m) - f_2'(m) \\ R_1(m) = F_1(m+1) - f_1(m) & R_2(m) = F_2(m+1) - f_2(m), \end{array}$$

which is derived from the relations—

$$\left.\begin{array}{l} Q_i(m) - P_i(m+1) \\ R_i(m) - Q_i(m+1) \end{array}\right\} \text{are the same for } \lambda\,3064 \text{ and } \lambda\,2811$$

$R_i(m) - P_i(m)$ are the same for λ 3064 II and λ 2811 I

$Q_i(m) - P_i(m+1) \neq R_i(m) - Q_i(m+1)$ in one band.

(3) As is well known, the lines do not follow Deslandres's rule for small values of m. There must therefore be a component of the electronic impulse along the axis of figure as well as one perpendicular to it.[5] The terms cannot be represented by the formula of Kramers and Pauli, or by the modification of it with which Kratzer[6] succeeded in representing the terms of the (C + H) bands. This shows that the electronic impulse cannot be connected quasi-rigidly with the molecule. It seems that the electronic impulse has a precession which increases with growing m.

(4) Fortrat[7] showed that most of the lines are accompanied by satellites. It is very probable that these satellites arise from the same quantum states of the molecule as the lines themselves, which indicates that they are also combinations between the terms given above. The three satellites of Q_2 are then, for example,

$$F_1(m) - f_2'(m) \qquad F_1(m) - f_2(m) \qquad F_2(m) - f_2(m)$$

The precision of the measurements, however, does not permit of deciding this question with certainty. It is not impossible that there are other terms slightly different from the former ones which are responsible for the satellites.

Hafnium Oxide in Tungsten Filaments.

IT has been known for a long time that perfectly pure tungsten cannot be used for the manufacture of filaments for electric lamps on account of its "off-setting" structure due to recrystallisation. It has been found also that recrystallisation can be essentially influenced by suitable additions. Thus, for example, thorium oxide or silicon oxide can be used with good results.

By mixing tungsten oxide with a solution of hafnium nitrate, evaporating the latter to dryness, heating the product obtained and reducing it then with hydrogen, tungsten powder is formed, having a definite content of hafnium oxide. In my experiments the latter was comprised between 0·1 and 3 per cent.

During the subsequent sintering operation in hydrogen to which the compressed and heated rod is submitted, a small part of the hafnium oxide is reduced, and the hafnium produced combines with the tungsten. During the subsequent swaging operation, this formation of a solid solution causes difficulties which can be easily obviated by using nitrogen or rare gases instead of hydrogen. In this case the swaging and drawing operation is readily effected.

The hafnium oxide is distinguished by its high melting-point and its low vapour pressure at high temperatures, so that it has proved to be a suitable addition to tungsten for filaments. The vapour tension at the temperature of the sintering operation is so low that no evaporation whatever of hafnium oxide could be ascertained.

Citrus Fruit and Scurvy.

IN "Purchas his Pilgrimage or Relations of the World and the Religions observed in al Ages and Places discovered" there are some interesting references to the disease scurvy. The edition I possess is the third, dated 1617; our Public Library in Melbourne having only the fourth, dated 1626.

On page 865 of this third edition the following statement occurs: "The Scorbute so weakened their men, that they were not able to hoise (*sic*) out their boats, except in the Generalls ship, whose men (drinking euery morning three spoonefuls of the iuice of Limons) were healthfull."

Again, on page 1086 there is a description of scurvy with a marginal printed note as follows: "Oranges, Limons, and the like are excellent remedies to this disease."

I regret I have not access to the first and second editions of the work, but as it is, this surely constitutes one of the earliest references to the citrus cure or prevention of scurvy.

Australopithecus africanus: The Man-Ape of South Africa.

By Prof. RAYMOND A. DART, University of the Witwatersrand, Johannesburg, South Africa.

TOWARDS the close of 1924, Miss Josephine Salmons, student demonstrator of anatomy in the University of the Witwatersrand, brought to me the fossilised skull of a cercopithecid monkey which, through her instrumentality, was very generously loaned to the Department for description by its owner, Mr. E. G. Izod, of the Rand Mines Limited. I learned that this valuable fossil had been blasted out of the limestone cliff formation—at a vertical depth of 50 feet and a horizontal depth of 200 feet—at Taungs, which lies 80 miles north of Kimberley on the main line to Rhodesia, in Bechuanaland, by operatives of the Northern Lime Company. Important stratigraphical evidence has been forthcoming recently from this district concerning the succession of stone ages in South Africa (Neville Jones, Jour. Roy. Anthrop. Inst., 1920), and the feeling was entertained that this lime deposit, like that of Broken Hill in Rhodesia, might contain fossil remains of primitive man.

I immediately consulted Dr. R. B. Young, professor of geology in the University of the Witwatersrand, about the discovery, and he, by a fortunate coincidence, was called down to Taungs almost synchronously to investigate geologically the lime deposits of an adjacent farm. During his visit to Taungs, Prof. Young was enabled, through the courtesy of Mr. A. F. Campbell, general manager of the Northern Lime Company, to inspect the site of the discovery and to select further samples of fossil material for me from the same formation. These included a natural cercopithecid endocranial cast, a second and larger cast, and some rock fragments disclosing portions of bone. Finally, Dr. Gordon D. Laing, senior lecturer in anatomy, obtained news, through his friend Mr. Ridley Hendry, of another primate skull from the same cliff. This cercopithecid skull, the possession of Mr. De Wet, of the Langlaagte Deep Mine, has also been liberally entrusted by him to the Department for scientific investigation.

FIG. 1.—Norma facialis of *Australopithecus africanus* aligned on the Frankfort horizontal.

The cercopithecid remains placed at our disposal certainly represent more than one species of catarrhine ape. The discovery of Cercopithecidæ in this area is not novel, for I have been informed that Mr. S. Haughton has in the press a paper discussing at least one species of baboon from this same spot (Royal Society of South Africa). It is of importance that, outside of the famous Fayûm area, primate deposits have been found on the African mainland at Oldaway (Hans Reck, *Sitzungsbericht der Gesellsch. Naturforsch. Freunde*, 1914), on the shores of Victoria Nyanza (C. W. Andrews, *Ann. Mag. Nat. Hist.*, 1916), and in Bechuanaland, for these discoveries lend promise to the expectation that a tolerably complete story of higher primate evolution in Africa will yet be wrested from our rocks.

In manipulating the pieces of rock brought back by Prof. Young, I found that the larger natural endocranial cast articulated exactly by its fractured frontal extremity with another piece of rock in which the broken lower and posterior margin of the left side of a mandible was visible. After cleaning the rock mass, the outline of the hinder and lower part of the facial skeleton came into view. Careful development of the solid limestone in which it was embedded finally revealed the almost entire face depicted in the accompanying photographs.

It was apparent when the larger endocranial cast was first observed that it was specially important, for its size and sulcal pattern revealed sufficient similarity with those of the chimpanzee and gorilla to demonstrate that one was handling in this instance an anthropoid and not a cercopithecid ape. Fossil anthropoids have not hitherto been recorded south of the Fayûm in Egypt, and living anthropoids have not been discovered in recent times south of Lake Kivu region in Belgian Congo, nearly 2000 miles to the north, as the crow flies.

All fossil anthropoids found hitherto have been known only from mandibular or maxillary fragments, so far as crania are concerned, and so the general appearance of the types they represented has been unknown; consequently, a condition of affairs where virtually the whole face and lower jaw, replete with teeth, together with the major portion of the brain pattern, have been preserved, constitutes a specimen of unusual value in fossil anthropoid discovery. Here, as in *Homo rhodesiensis*, Southern Africa has provided documents of higher primate evolution that are amongst the most complete extant.

Apart from this evidential completeness, the specimen is of importance because it exhibits an extinct race of apes *intermediate between living anthropoids and man*.

In the first place, the whole cranium displays *humanoid* rather than anthropoid lineaments. It is markedly dolichocephalic and leptoprosopic, and manifests in a striking degree the *harmonious relation* of calvaria to face emphasised by Pruner-Bey. As Topinard says, "A cranium elongated from before backwards, and at the same time elevated, is already in harmony by itself; but if the face, on the other hand, is elongated from above downwards, and narrows, the harmony is complete." I have assessed roughly the difference in the relationship of the glabella-gnathion facial length to the glabella-inion calvarial length in recent African anthropoids of an age comparable with that of this specimen (depicted in Duckworth's "Anthropology and Morphology," second edition, vol. i.), and find that, if the glabella-inion length be regarded in all three as 100, then the glabella-gnathion length in the young chimpanzee is approximately 88, in the young gorilla 80, and in this fossil 70, which proportion suitably demonstrates the enhanced

relationship of cerebral length to facial length in the fossil (Fig. 2)

The glabella is tolerably pronounced, but any traces of the salient supra-orbital ridges, which are present even in immature living anthropoids, are here entirely absent. Thus the relatively increased glabella-inion measurement is due to brain and not to bone. Allowing 4 mm for the bone thickness in the inion region, that measurement in the fossil is 127 mm.; *i.e.* 4 mm. less than the same measurement in an adult chimpanzee in the Anatomy Museum at the University of the Witwatersrand. The orbits are not in any sense detached from the forehead, which rises steadily from their margins in a fashion amazingly human The interorbital width is very small (13 mm.) and the ethmoids are not blown out laterally as in modern African anthropoids This lack of ethmoidal expansion causes the lacrimal fossæ to face posteriorly and to lie relatively far back in the orbits, as in man The orbits, instead of being subquadrate as in anthropoids, are almost circular, furnishing an orbital index of 100, which is well within the range of human variation (Topinard, "Anthropology"). The malars, zygomatic arches, maxillæ, and mandible all betray a delicate and humanoid character The facial prognathism is relatively slight, the gnathic index of Flower giving a value of 109, which is scarcely greater than that of certain Bushmen (Strandloopers) examined by Shrubsall The nasal bones are not prolonged below the level of the lower orbital margins, as in anthropoids, but end above these, as in man, and are incompletely fused together in their lower half. Their maximum length (17 mm) is not so great as that of the nasals in *Eoanthropus dawsoni* They are depressed in the median line, as in the chimpanzee, in their lower half, but it seems probable that this depression has occurred post-mortem, for the upper half of each bone is arched forwards (Fig 1). The nasal aperture is small and is just wider than it is high (17 mm × 16 mm.) There is no nasal spine, the floor of the nasal cavity being continuous with the anterior aspect of the alveolar portions of the maxillæ, after the fashion of the chimpanzee and of certain New Caledonians and negroes (Topinard, *loc. cit*).

In the second place, the dentition is *humanoid* rather than anthropoid The specimen is juvenile, for the

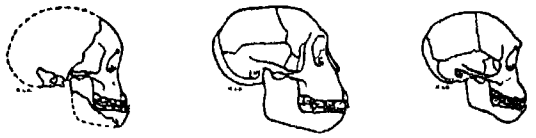

FIG. 2.—Cranial form in living anthropoids of similar age (after Duckworth) and in the new fossil For this comparison, the fossil is regarded as having the same calvarial length as the gorilla.

first permanent molar tooth only has erupted in both jaws on both sides of the face; *i.e.* it corresponds anatomically with a human child of six years of age. Observations upon the milk dentition of living primates are few, and only one molar tooth of the deciduous dentition in one fossil anthropoid is known (Gregory, "The Origin and Evolution of the Human Dentition," 1920). Hence the data for the necessary comparisons are meagre, but certain striking features of the milk dentition of this creature may be mentioned. The tips of the canine teeth transgress very slightly (0·5-0·75 mm) the general margin of the teeth in each jaw, *i.e.* very little more than does the human milk canine. There is no diastema whatever between the premolars and canines on either side of the lower jaw, such as is present in the deciduous dentition of living anthropoids; but the canines in this jaw come, as in the human jaw, into alignment with the incisors (Gregory, *loc. cit.*). There is a diastema (2 mm on the right side, and 3 mm. on the left side) between the canines and lateral incisors of the upper jaw, but seeing, first, that the incisors are narrow, and, secondly, that diastemata (1 mm-1·5 mm) occur between the central incisors of the upper jaw and between the medial and lateral incisors of both sides in the lower jaw, and, thirdly, that some separation of the milk teeth takes place even in mankind (Tomes, "Dental Anatomy," seventh edition) during the establishment of the permanent dentition, it is evident that the diastemata which occur in the upper jaw are small. The lower canines, nevertheless, show wearing facets both for the upper canines and for the upper lateral incisors.

FIG. 3.—Norma lateralis of *Australopithecus africanus* aligned on the Frankfort horizontal.

The incisors as a group are irregular in size, tend to overlap one another, and are almost vertical, as in man; they are not symmetrical and well spaced, and do not project forwards markedly, as in anthropoids. The upper lateral incisors do project forwards to some extent and perhaps also do the upper central incisors very slightly, but the lateral lower incisors betray no evidence of forward projection, and the central lower incisors are not even vertical as in most races of mankind, but are directed slightly backwards, as *sometimes* occurs in man Owing to these remarkably human characters displayed by the deciduous dentition, when contour tracings of the upper jaw are made, it is found that the jaw and the teeth, as a whole, take up a parabolic arrangement comparable only with that presented by mankind amongst the higher primates. These facts, together with the more minute anatomy of the teeth, will be illustrated and discussed in the memoir which is in the process of elaboration concerning the fossil remains.

In the third place, the mandible itself is *humanoid* rather than anthropoid. Its ramus is, on the whole, short and slender as compared with that of anthropoids, but the bone itself is more massive than that of a human being of the same age. Its symphyseal region is virtually complete and reveals anteriorly a more vertical outline than is found in anthropoids or even in the jaw of Piltdown man. The anterior symphyseal surface is scarcely less vertical than that of Heidelberg man. The posterior symphyseal surface in living

anthropoids differs from that of modern man in possessing a pronounced posterior prolongation of the lower border, which joins together the two halves of the mandible, and so forms the well-known *simian shelf* and above it a deep genial impression for the attachment of the tongue musculature In this character, *Eoanthropus dawsoni* scarcely differs from the anthropoids, especially the chimpanzee; but this new fossil betrays no evidence of such a shelf, the lower border of the mandible having been massive and rounded after the fashion of the mandible of *Homo heidelbergensis*.

FIG 4.—Norma basalis of *Australopithecus africanus* aligned on the Frankfort horizontal

That hominid characters were not restricted to the face in this extinct primate group is borne out by the relatively forward situation of the foramen magnum. The position of the basion can be assessed within a few millimetres of error, because a portion of the right exoccipital is present alongside the cast of the basal aspect of the cerebellum Its position is such that the basi-prosthion measurement is 89 mm, while the basi-inion measurement is at least 54 mm This relationship may be expressed in the form of a "head-balancing" index of 60·7. The same index in a baboon provides a value of 41·3, in an adult chimpanzee 50·7, in Rhodesian man 83 7, in a dolichocephalic European 90·9, and in a brachycephalic European 105 8. It is significant that this index, which indicates in a measure the poise of the skull upon the vertebral column, points to the assumption by this fossil group of an attitude appreciably more erect than that of modern anthropoids. The improved poise of the head, and the better posture of the whole body framework which accompanied this alteration in the angle at which its dominant member was supported, is of great significance. It means that a greater reliance was being placed by this group upon the feet as organs of progression, and that the hands were being freed from their more primitive function of accessory organs of locomotion. Bipedal animals, their hands were assuming a higher evolutionary rôle not only as delicate tactual, examining organs which were adding copiously to the animal's knowledge of its physical environment, but also as instruments of the growing intelligence in carrying out more elaborate, purposeful, and skilled movements, and as organs of offence and defence. The latter is rendered the more probable, in view, first, of their failure to develop massive canines and hideous features, and, secondly, of the fact that even living baboons and anthropoid apes can and do use sticks and stones as implements and as weapons of offence ("Descent of Man," p. 81 *et seq.*).

Lastly, there remains a consideration of the endocranial cast which was responsible for the discovery of the face. The cast comprises the right cerebral and cerebellar hemispheres (both of which fortunately meet the median line throughout their entire dorsal length) and the anterior portion of the left cerebral hemisphere. The remainder of the cranial cavity seems to have been empty, for the left face of the cast is clothed with a picturesque lime crystal deposit; the vacuity in the left half of the cranial cavity was probably responsible for the fragmentation of the specimen during the blasting. The cranial capacity of the specimen may best be appreciated by the statement that the length of the cavity could not have been less than 114 mm., which is 3 mm. greater than that of an adult chimpanzee in the Museum of the Anatomy Department in the University of the Witwatersrand, and only 14 mm less than the greatest length of the cast of the endocranium of a gorilla chosen for casting on account of its great size Few data are available concerning the expansion of brain matter which takes place in the living anthropoid brain between the time of eruption of the first permanent molars and the time of their becoming adult. So far as man is concerned, Owen ("Anatomy of Vertebrates," vol iii) tells us that "The brain has advanced to near its term of size at about ten years, but it does not usually obtain its full development till between twenty and thirty years of age" R Boyd (1860) discovered an increase in weight of nearly 250 grams in the brains of male human beings after they had reached the age of seven years It is therefore reasonable to believe that the adult forms typified by our present specimen possessed brains which were larger than that of this juvenile specimen, and equalled, if they did not actually supersede, that of the gorilla in absolute size

Whatever the total dimensions of the adult brain may have been, there are not lacking evidences that the brain in this group of fossil forms was distinctive in type and was an instrument of greater intelligence that that of living anthropoids. The face of the endocranial cast is scarred unfortunately in several places (cross-hatched in the dioptographic tracing—see Fig. 5). It is evident that the relative proportion

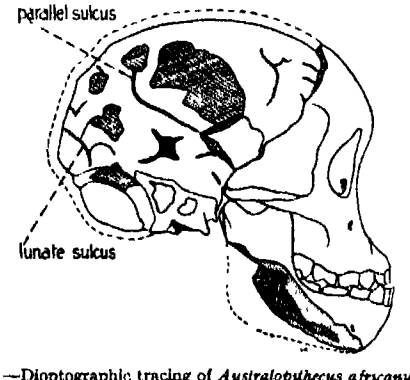

FIG 5.—Dioptographic tracing of *Australopithecus africanus* (right side), × ½

of cerebral to cerebellar matter in this brain was greater than in the gorilla's. The brain does not show that general pre- and post-Rolandic flattening characteristic of the living anthropoids, but presents a rounded and well-filled-out contour, which points to a symmetrical and balanced development of the faculties of associative memory and intelligent activity. The pithecoid type of parallel sulcus is preserved, but the sulcus lunatus has been thrust backwards towards the occipital pole by a pronounced general

bulging of the parieto-temporo-occipital association areas.

To emphasise this matter, I have reproduced (Fig. 6) superimposed coronal contour tracings taken at the widest part of the parietal region in the gorilla endocranial cast and in this fossil. Nothing could illustrate better the mental gap that exists between living anthropoid apes and the group of creatures which the fossil represents than the flattened atrophic appearance of the parietal region of the brain (which lies between the visual field on one hand, and the tactile and auditory fields on the other) in the former and its surgent vertical and dorso-lateral expansion in the latter The expansion in this area of the brain is the more significant in that it explains the posterior *humanoid* situation of the sulcus lunatus It indicates (together with the narrow interorbital interval and human characters of the orbit) the fact that this group of beings, having acquired the faculty of stereoscopic vision, had profited beyond living anthropoids by setting aside a relatively much larger area of the cerebral cortex to

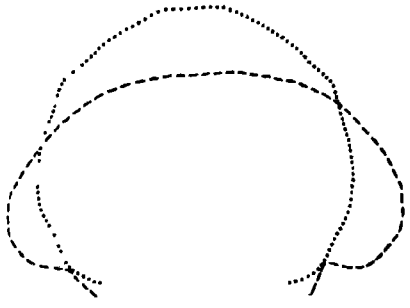

FIG. 6.—Contour tracings of coronal sections through the widest part of the parietal region of the endocranial casts in Australopithecus .... and in a gorilla ----

serve as a storehouse of information concerning their objective environment as its details were simultaneously revealed to the senses of vision and touch, and also of hearing They possessed to a degree unappreciated by living anthropoids the use of their hands and ears and the consequent faculty of associating with the colour, form, and general appearance of objects, their weight, texture, resilience, and flexibility, as well as the significance of sounds emitted by them In other words, their eyes saw, their ears heard, and their hands handled objects with greater meaning and to fuller purpose than the corresponding organs in recent apes They had laid down the foundations of that discriminative knowledge of the appearance, feeling, and sound of things that was a necessary milestone in the acquisition of articulate speech.

There is, therefore, an ultra-simian quality of the brain depicted in this immature endocranial cast which harmonises with the ultra-simian features revealed by the entire cranial topography and corroborates the various inferences drawn therefrom. The two thousand miles of territory which separate this creature from its nearest living anthropoid cousins is indirect testimony to its increased intelligence and mastery of its environment It is manifest that we are in the presence here of a pre-human stock, neither chimpanzee nor gorilla, which possesses a series of differential characters not encountered hitherto in any anthropoid stock. This complex of characters exhibited is such that it cannot be interpreted as belonging to a form ancestral to any living anthropoid. For this reason, we may be equally confident that there can be no question here of a primitive anthropoid stock such as has been recovered from the Egyptian Fayum. Fossil anthropoids, varieties of Dryopithecus, have been retrieved in many parts of Europe, Northern Africa, and Northern India, but the present specimen, despite its youth, cannot be confused with anthropoids having the dryopithecid dentition. Other fossil anthropoids from the Siwalik hills in India (Miocene and Phocene) are known which, according to certain observers, may be ancestral to modern anthropoids and even to man

Whether our present fossil is to be correlated with the discoveries made in India is not yet apparent; that question can only be solved by a careful comparison of the permanent molar teeth from both localities. It is obvious, meanwhile, that it represents a fossil group distinctly advanced beyond living anthropoids in those two dominantly human characters of facial and dental recession on one hand, and improved quality of the brain on the other Unlike Pithecanthropus, it does not represent an ape-like man, a caricature of precocious hominid failure, but a creature well advanced beyond modern anthropoids in just those characters, facial and cerebral, which are to be anticipated in an extinct link between man and his simian ancestor. At the same time, it is equally evident that a creature with anthropoid brain capacity, and lacking the distinctive, localised temporal expansions which appear to be concomitant with and necessary to articulate man, is no true man. It is therefore logically regarded as a man-like ape. I propose tentatively, then, that a new family of *Homo-simiadæ* be created for the reception of the group of individuals which it represents, and that the first known species of the group be designated *Australopithecus africanus*, in commemoration, first, of the extreme southern and unexpected horizon of its discovery, and secondly, of the continent in which so many new and important discoveries connected with the early history of man have recently been made, thus vindicating the Darwinian claim that Africa would prove to be the cradle of mankind.

It will appear to many a remarkable fact that an ultra-simian and pre-human stock should be discovered, in the first place, at this extreme southern point in Africa, and, secondly, in Bechuanaland, for one does not associate with the present climatic conditions obtaining on the eastern fringe of the Kalahari desert an environment favourable to higher primate life. It is generally believed by geologists (*vide* A. W. Rogers, "Post-Cretaceous Climates of South Africa," *South African Journal of Science*, vol. xix., 1922) that the climate has fluctuated within exceedingly narrow limits in this country since Cretaceous times. We must therefore conclude that it was only the enhanced cerebral powers possessed by this group which made their existence possible in this untoward environment.

In anticipating the discovery of the true links between the apes and man in tropical countries, there has been a tendency to overlook the fact that, in the luxuriant forests of the tropical belts, Nature was supplying with profligate and lavish hand an easy and sluggish solution, by adaptive specialisation, of the

problem of existence in creatures so well equipped mentally as living anthropoids are. For the production of man a different apprenticeship was needed to sharpen the wits and quicken the higher manifestations of intellect—a more open veldt country where competition was keener between swiftness and stealth, and where adroitness of thinking and movement played a preponderating rôle in the preservation of the species. Darwin has said, "no country in the world abounds in a greater degree with dangerous beasts than Southern Africa," and, in my opinion, Southern Africa, by providing a vast open country with occasional wooded belts and a relative scarcity of water, together with a fierce and bitter mammalian competition, furnished a laboratory such as was essential to this penultimate phase of human evolution.

In Southern Africa, where climatic conditions appear to have fluctuated little since Cretaceous times, and where ample dolomitic formations have provided innumerable refuges during life, and burial-places after death, for our troglodytic forefathers, we may confidently anticipate many complementary discoveries concerning this period in our evolution.

In conclusion, I desire to place on record my indebtedness to Miss Salmons, Prof. Young, and Mr Campbell, without whose aid the discovery would not have been made; to Mr. Len Richardson for providing the photographs; to Dr Laing and my laboratory staff for their willing assistance; and particularly to Mr. H. Le Helloco, student demonstrator in the Anatomy Department, who has prepared the illustrations for this preliminary statement

Biographical Byways.[1]

By Sir ARTHUR SCHUSTER, F.R.S.

6. S. P. LANGLEY (1831–1906)

LANGLEY'S invention of the bolometer, and his pioneer work in the construction of the flying machine, are achievements sufficiently great to ensure a reputation which will outweigh the recollection of defects due to an exaggerated consciousness of dignity, accompanied by a marked inability to see the humorous side of things. I first met Langley on the occasion of the total solar eclipse in August 1878, when he established an observing station on the top of Pike's Peak in order to obtain, if possible, a measure of the thermal radiation of the solar corona. Unfortunately, he suffered severely from mountain sickness, and had to be carried down before the day of the eclipse.

In the following year, Langley visited England and expressed to me the desire to become acquainted with Clerk Maxwell. I was working at the Cavendish Laboratory at the time, and was able to assure him that Maxwell would be interested to meet him as he had, in my presence, referred in very eulogistic terms to a method proposed by Langley to eliminate the personal equation in transit observations. Clerk Maxwell was just then editing Cavendish's scientific manuscripts, and conscientiously repeated every experiment that was described in them. He was specially interested in the method which Cavendish had devised for estimating the relative intensities of two electric currents, by sending the currents through his body and comparing the muscular contraction felt on interrupting the currents: "Every man his own galvanometer," as Maxwell expressed it. When Langley arrived, I took him to the room where Maxwell stood in his shirt sleeves with each hand in a basin filled with water through which the current was laid. Enthusiastic about the unexpected accuracy of the experiment, and assuming that every scientific man was equally interested, he tried to persuade Langley to take off his coat and have a try. This was too much for Langley's dignity; he did not even make an effort to conceal his anger, and on leaving the laboratory he turned round and said to me: "When an English man of science comes to the United States we do not treat him like that." I explained that, had he only had a little patience and entered into the spirit of Maxwell's experiment, the outcome of his visit would have been more satisfactory.

As an experimenter Langley takes a high rank, though the numerical results he derived were sometimes based on calculations that were not entirely free from defects. This led him occasionally to an optimistic judgment of their accuracy. In sending out an assistant to repeat his measurement of the so-called solar constant, which expresses the total solar radiation in certain units, his final words to him were: "Remember that the nearer your result approaches the number 3, the higher will be my opinion of the accuracy of your observations." The assistant, who since then has himself attained a high position among American men of science, fortunately was a man of independent judgment and skilful both in taking and reducing his observations, with the result that the number 3 is now altogether discredited.

Obituary.

DR. J. M. ELLIS MCTAGGART.

THE news of the sudden death of Dr. McTaggart on January 18, at the early age of fifty-eight, came as a great shock to his numerous colleagues and friends both in Cambridge and throughout Great Britain. He had, indeed, resigned his lectureship in Trinity College, Cambridge, more than a year ago in order to devote more time to literary work; but he went on giving some of the courses of lectures he had been accustomed to give, and his interest in everything that pertained to the University continued to be as keen as ever. His Friday evening lectures, open to students of all schools, have been for many years past a Cambridge institution; and various stories are related of his acuteness, resource, and ready wit in endeavouring to initiate the *profanum vulgus* in the problems of metaphysics. In the affairs of his College and in those of the University he took a leading and conspicuous part, bringing to bear upon every issue a fearless independence of judgment, which won for him the

respect and esteem even of those to whom he was most opposed in opinion. In politics he was strongly conservative, although here again he never allowed himself to be fettered by party ties but pursued a path distinctly his own.

McTaggart was a born metaphysician Even as a promising and favourite pupil of J. M Wilson at Clifton, he is said to have displayed dialectical skill, and, on entering Trinity College, Cambridge, he began a brilliant career as an undergraduate, taking his degree as alone in the first class in the Moral Sciences Tripos of 1888 In 1891 he was elected a fellow of Trinity, having submitted as a dissertation the substance of what now forms the first four chapters of the book he published in 1896 (dedicated "to Miss Frances Power Cobbe, with much gratitude"), entitled "Studies in Hegelian Dialectic" There followed in 1901 "Studies in Hegelian Cosmology" An early draft of the last chapter on "The Further Determination of the Absolute" had been previously printed, in 1894, for "private circulation only", and in the preface to this pamphlet the author characteristically observed: "I hoped that an attempt to explain my position to a few of my teachers and fellow-students might produce criticisms or refutations which should be profitable either in improving or preventing any further work on my part" Still another book on Hegel -"A Commentary on Hegel's Logic"—appeared in 1910 Here we are told that Hegel had been the chief object of McTaggart's life for twenty-one years, and he expresses his conviction that Hegel had penetrated further into the true nature of reality than any philosopher either before or after him A more popular work, "Some Dogmas of Religion," saw the light in 1906, in it many novel views were propounded and they elicited no small amount of discussion Lastly, in 1921, McTaggart published the first volume of what was evidently intended to be his *magnum opus*, on "The Nature of Existence" It is understood that he has left the manuscript of the remaining volume in a condition that will enable it to be put into print, so that we shall fortunately not be deprived of the outcome of his maturest reflection.

To indicate the distinctive features of McTaggart's speculation in a few words is scarcely possible In the 'Commentary" mentioned above he stated his belief that the next task of philosophy will be to make a fresh investigation of the nature of reality "by a dialectic method substantially, though not entirely, the same as Hegel's", and, in his last book, he attempted to show how that task is to be fulfilled His method differs from Hegel's principally in neither accepting a *triadic* division of categories nor the partial falsehood of the lower categories. In the first part of his system, that dealing with the general nature of the existent, he admitted only two empirical premises—that "something exists" and that "what exists is differentiated"—and the rest, he claimed, is entirely *a priori*, in the second part, the results obtained in the first part were to be applied to the facts which empirical observation reveals, or appears to reveal.

McTaggart's idealism was not of the epistemological type, it did not rest, that is to say, upon any assumed dependence of the object known upon the knowing subject, it was what he was in the habit of calling ontological idealism, as based upon the ground that nothing exists but spirit. Spirituality he defined as the quality of having content, such content being the content of one or more selves; and he held that the only existent realities are selves, groups of selves, and parts of selves. Among these selves there might conceivably be one self whose volitions had the appearance of influencing the rest of the universe so profoundly that he would properly be called a god; but McTaggart could find no evidence which would make his existence probable. Indeed, if the universe consist of a system of selves, and if that system be a unity which possesses spiritual significance and value, there would be, he urged, no need of a directing mind to account for the traces of order in it In any case, if the universe be a society of selves, it cannot *be* a self; and, therefore, the *Absolute* cannot be God. Time, according to McTaggart, is an appearance which will ultimately merge into the timeless or the eternal Finite selves will go on existing after death until they reach the end of the time series They cannot be said to be immortal in the ordinary sense, but their lives will not really end, although their unendingness cannot be an unending duration in time.

G DAWES HICKS

MR. C. H. WORDINGHAM

MR CHARLES HENRY WORDINGHAM, who died on January 28 at the age of fifty-eight years, was well known as an electrical engineer He was born at Twickenham in 1866, and was educated at King's College School and at King's College, London. He served his apprenticeship under Dr John Hopkinson. He then joined the United Telephone Company, where his work consisted mainly in assisting with the erection of telephone exchanges. From 1889 to 1892 he was an engineer at the Grosvenor Gallery Generating Station of the London Electric Supply Corporation, where he was associated with Dr. Ferranti and Mr Partridge in carrying out many of the pioneering experiments which led the way to such important developments. During this period also he was head of the meter testing department and devised methods of testing switches and fuses which were very useful in practical work. In 1892 he again became an assistant to Dr. Hopkinson and supervised the erection of the electric lighting stations at Manchester and Whitehaven In 1894 he became chief engineer to the electricity works of the Manchester Corporation, and for the next seven years devoted himself whole-heartedly to developing the station.

In these early days many installations were laid down most carelessly, and the material employed was unsuitable. Wordingham established a testing department at the works and insisted that all the switches, fuses and other material used by his consumers should pass a standard test. He encountered great opposition at the start, but ultimately the manufacturers saw that it was to their advantage to have their devices tested. During his stay in Manchester he superintended the conversion of some 100 miles of tramways from horse to electric traction, and equipped 38 miles of new tramway.

Wordingham left Manchester in 1901 to practise as a

consulting engineer, and in 1903 he was offered and accepted the post of electrical engineer-in-chief to the Admiralty. Here he was responsible for the electrical equipment of all his Majesty's ships and for the electrical lighting and power used in the dockyards, including Rosyth and all the naval air stations. In 1918 he left the Navy and resumed his consulting practice. He was consulted by many local authorities on traction and lighting projects. He also gave expert evidence and supervised the erection of several power stations.

Wordingham served for many years on the council of the Institution of Electrical Engineers and no one took a greater interest in practically all the committees. He was president of the Institution in 1917 and 1918, and laid down a standard of work which subsequent presidents have found it difficult to equal He was very enthusiastic that the Institution should found a Proving House for all electrical apparatus and material, but many difficulties stood in the way. During his presidentship he helped to found the Society of Radiographers, which is doing useful work. He made many contributions to the technical journals and wrote a useful book on "Central Electrical Stations"

He was president of the Junior Institution of Engineers and always took the greatest interest in young engineers, doing his utmost to encourage them

A vast amount of work was also done by Wordingham in connexion with the Engineering Standards Association, being chairman of the Electrical Sectional Committees He also took endless pains in getting the Wiring Rules of the Institution of Electrical Engineers accepted by the authorities. He has died at a comparatively early age, leaving many of the projects in which he was enthusiastically interested half finished He was very popular with his colleagues, and he will be grievously missed by every electrical engineer

A R

Mr George Abbott.

Geology perhaps more than any other science needs all the assistance which careful amateurs can bring to the total sum of knowledge. Men living on the spot are of the greatest service to the official geologists when a re-survey takes place. George Abbott was one of the most painstaking of local geologists, whose help was always at the service of those who needed it. Born on March 25, 1844, he was in his eighty-first year when he died on January 12 at Tunbridge Wells, where he had lived since 1878 Scattered in various publications are many of his contributions to geology, but he was particularly interested in the various rock-forms which so often resemble organised life. From the magnesian limestone of Fulwell he obtained most of his specimens, and these he classified in so clear a manner that one was able to realise from his tables the series of stages by which such forms gradually grew to their familiar pseudo-organic shapes

In 1896, in conjunction with the Rev T R. R. Stebbing, Abbott conceived the happy thought of creating a union of scientific and similar societies in the south-east of England for mutual help, and the first two of the South-Eastern Union's Annual Congresses were held at Tunbridge Wells. The Union grew into a vigorous organisation and has held its annual congresses regularly ever since, whilst its annual proceedings, *The South-Eastern Naturalist*, is now accepted as a responsible scientific publication Some years later he founded a Geological Physics Society, but here apparently was a society which was not needed, for after a few years of vicissitude it ceased to exist. Its work is being done by other organisations, but as a protest against the overpowering study of palæontology it performed some useful work.

Abbott had suffered a good deal during the last few years, and his favourite study, apart from his medical duties, was a great comfort in the time that he was laid by He founded the local natural history society, and supplied many specimens to the elementary schools of the borough, on the Town Council of which he served for some years He also established the Eye and Ear Hospital at Tunbridge Wells, and was Hon. Surgeon from 1878 to 1886

We regret to announce the following deaths

Prof W A Haswell, F R S., emeritus professor of biology in the University of Sydney, and author, with the late Prof T. Jeffrey Parker, of "A Text Book of Zoology," aged seventy

Dr N Kulchitsky, lecturer in histology at University College, London, and formerly professor of anatomy in the University of Kharkov, on January 29

Dr. D B Spooner, deputy director of archæology in India since 1919, on January 30

Prof Hermann Schunck, a former director of the Badische Anilin- und Soda-Fabrik at Ludwigshafen, who retired in 1923, on January 8, at Solln near Munich

Current Topics and Events.

Elsewhere in this issue appears an account of a remarkable discovery which appears to afford *prima facie* evidence of the occurrence at a remote period in South Africa of a pre-human stock, neither chimpanzee nor gorilla, and possessing a series of characters differentiating it from any anthropoid hitherto known. Fossilised fragments from a limestone cliff formation at Taungs, 80 miles north of Kimberley, in Bechuanaland, when fitted together, have revealed a natural endocranial cast with almost the entire face of what at first sight appeared to be an anthropoid, but on closer examination is found by Prof. Dart to exhibit humanoid rather than anthropoid characters. The occurrence of a fossil anthropoid so far south would in itself be sufficiently remarkable, but the interest and importance of this discovery is enhanced by its remarkable divergence from the anthropoid and its approximation to the human stock. Not only is this exhibited in the character of the cranium as a whole, but it is also apparent in the formation of the brain, so far as this is indicated by the endocranial cast. The position of the foramen magnum, if correctly estimated, in itself would indicate that this sub-human type was well on the way towards acquiring the upright posture, and the inference of an increase in intelligence which would follow upon a

freer use of the fore-limbs is supported by the development of the association areas of the brain, which is such as to indicate a marked advance in the growth of intellect. So far are we taken by Prof Dart's preliminary report and the photographs which accompany it A detailed examination of the evidence upon which his conclusions are based must await the publication of the monograph now in course of preparation. Within recent years, South Africa, in the discovery of the Boskop and Rhodesian skulls, has added remarkable chapters to the history of early man; but even the interest of Rhodesian man may well be eclipsed if the claim of *Australopithecus africanus* be substantiated. In this event, we shall have advanced one stage further, and that a stage of the greatest importance, in the quest for the cradle of mankind, whether that eventually prove to have been in Africa or elsewhere

THE series of extracts from Dr Birch's "History of the Royal Society," that have been appearing in NATURE week by week during the past year, reached a conclusion with the article published last week. But to Lancelot, Lancelot succeeds, "Early Science at the Royal Society" will be followed by "Early Science at Oxford," a somewhat similar series of extracts taken from the Minute Books of the Philosophical Society at Oxford between the years 1683 and 1690 By some the Oxford Society is regarded as the origin from which the Royal Society sprang. Certainly it was a fully organised body, with a constitution and officers, more than ten years before the London Society received its first charter, or recorded proceedings; and even in the papers of the Royal Society itself there are occasional early references to "an ingenious assembly" meeting in Oxford. The gatherings were, however, somewhat irregular owing to the fact that the members having no proper meeting-house, had to rely upon private hospitality, which made it difficult for them to accumulate books or collections, or even to arrange experiments The building of the Ashmolean Museum, with a chemical laboratory in the basement and a room for the study of natural history on the first floor, provided the accommodation that was necessary for further progress, and on October 26, 1683, "The Company meeting in ye Naturall History School, desired Dr Wallis, to take on him ye trouble of ye Chair, and appointed Mr Musgrave to take ye Minutes of their Discourse." Extracts from Mr. Musgrave's minutes are now published for the first time

ON December 15 last the Foreign Secretary, in response to a question in the House of Commons asked by Mr A A. Somerville, M P. for Windsor, issued a Return giving full particulars of the Boxer Indemnity (Hansard's Debates, Dec. 25, 1924, p. 641, price 6d; or Christian Industrial Fellowship, 4 The Sanctuary, Westminster, price 1d.). The Return enumerates not only the Powers concerned and the annual quotas paid to each, but also, in the case of remitting Powers other than Great Britain, the operative instrument and the stated purposes of remission, together with the machinery set up. One notable point of this illuminating document is that all the other remitting Powers (United States, Japan, Russia, France) have defined the purposes of their remission by statute or other legislative process, leaving to committees the task of carrying into operation the purposes thus defined Another point common to all, except France, is that the purposes of remission are declared to be exclusively educational or cultural. even France makes a similar declaration, but its action is postponed until the debts of a state-guaranteed bank have been discharged. The remitted quotas—all of which continue until 1945—vary from 1,000,000*l* a year (Russia) to 150,000*l*. (United States), that being all that remains of her original share of 260,000*l* To Britain is due 400,000*l*. a year The German and the Austro-Hungarian quotas, 700,000*l*. and 30,000*l* respectively, were cancelled by the allies as a result of the War The China Indemnity Bill is down for second reading in the House of Commons on February 13 The Government will, it is understood, introduce the late Government's Bill, as amended in committee If, when the Bill becomes an Act, the present meaningless description of purposes is retained, an advisory committee, and not Parliament, will determine whether "educational or other" purposes shall, for example, be interpreted to include railways. It is hoped, however, that the Government may be induced so to define the purposes as to exclude this possibility, for though such a use of part of the fund might benefit a few contractors and employ a few engineers in China, it would certainly lower our prestige and alienate those for whom our remission of a just debt has been made.

PROF W J. DAKIN'S inaugural address on "The Teaching of Biology in Secondary Schools," delivered before the Liverpool Biological Society and published in vol xxxviii., 1924, of the Society's Transactions, is a forcible pleading for the inclusion of biology as a subject of general education in school curricula Not botany alone, or zoology alone; but the study of life-processes as manifested both in plants and in animals, the mutual relations of the members of the two kingdoms, and the bearings of both on human welfare—this is the type of biology that he advocates. Since in many schools botany is already taught, a large portion of the address is devoted to showing how zoology may, with a little foresight and slight expense, be likewise included in the teaching scheme. Difficulties that are feared, and objections that have been raised by some teachers, are discussed; and useful suggestions are offered by which apparent obstacles may be surmounted. An emphatic denial is given to the statement made in the Report of the Investigators of the Secondary School Examinations Council that "the principles of Biological Science can be better illustrated by means of botany, especially as physiology occupies a far more important part in the subject than in zoology, which does not readily lend itself to experimental treatment." There will doubtless be differences of opinion among teachers regarding the exact stage at which biology, in the full sense recommended by Prof. Dakins, can most

advantageously be introduced into the school time-table; but it is to be hoped that this address will be taken to heart and widely applied in those classes to which such teaching is appropriate.

DR. W. P. DAVEY, the research physicist of the General Electric Company of America, has produced a crystallised form of copper the electric conductivity of which is 13 per cent better than that of ordinary pure electrolytic copper. Prof. Bridgman, of Harvard, was the first to discover that copper could be produced in relatively large crystals by the method of slowly heating it in an electric furnace and then cooling it equally slowly. On December 31, Dr. Davey described to the American Physical Society his success in producing copper crystals nearly an inch in diameter and six inches long. These specimens could be bent without effort, but once bent they could not be straightened again This is attributed to the effect produced by the bending in upsetting the balance of the atoms of copper The crystals seem to readjust themselves into small crystals again, so that for all practical purposes it becomes a bar of ordinary copper and is equally inflexible. By X-ray examination it was shown that the prepared copper was simply one large crystal, the atoms being arranged in regular rows from end to end. When the crystal was hammered it lost its super-conductivity. The new copper has a greater conductivity than silver. At present its manufacture on a commercial scale is not feasible, but Dr. Davey thinks that the time is in sight when it can be used for ordinary dynamos and conducting mains As less copper would be required for a given service, it would cheapen the cost of conduits in underground work and of the towers required for overhead conductors.

SCIENTIFIC addresses by Sir Robert Hadfield are usually of a most comprehensive and enlightening kind, and that delivered by him before the Oxford University Junior Scientific Club on January 21 will delight all who see it in its published form. The address was entitled "Metallurgy and its Influence on Modern Progress," and it occupies about 190 pages, of which only a portion was read and illustrated by lantern slides and moving pictures Amongst the plates in the published volume is a particularly interesting one showing Roger Bacon (1214–1292), one of the early founders of scientific thought in Oxford; the illustration represents Bacon, who wrote letters "of the Secrets of Arts and Nature" to the Paris University, presenting a book to the Chancellor of that University. By kind permission of the War Office and Admiralty, Sir Robert was able to show, in the course of his address, a cinematograph picture, taken by himself and his staff, of loading and firing a 15-inch gun at the Government Proving Ground at Shoeburyness, including a view of the butt one sixteenth of a second later showing the impact on the plate; one half second later showing large numbers of fragments flying from the plate and the butt, and finally the unbroken projectile, weighing nearly one ton, after it had perforated the thick, hard-faced armour plate against which it was fired. The sections devoted to metallurgy in the book cover about one hundred pages, in which Sir Robert refers to the importance of iron in antiquity, and the rise and importance of alloy steels He gives a history of the invention by himself of manganese steel, silicon steel, and other alloy steels, and refers also to the value of heat treatment and the history of the pyrometer In concluding his address Sir Robert directed attention to the importance of effort, progress and international co-operation, and suggested that there should be an annual Science Day to impress upon the community the place of science in modern life.

SIR OLIVER LODGE'S third talk on "Ether and Reality," delivered on February 3 under the auspices of the British Broadcasting Co from the London Station, 2LO, was devoted to the electric charge and the means by which electric charges act on each other. The following are extracts from his instructive address.—Discoveries of the present century have shown (what had already been suspected by Faraday and Maxwell in the last century) that electric charges are discontinuous, like matter, that they exist as separate particles, although their field or region of influence extends throughout space. Moreover, electric particles or corpuscles are of two opposite kinds, which attract each other, and when very close together blot out each other's field at a distance and form a neutral combination Particles which attract each other need not fall into each other, any more than the planets fall into the sun The negative corpuscles can revolve round the positive, and thereby constitute a neutral group, with which we are familiar as an atom of matter. That is what an atom of matter is, that is what is meant by saying that matter is electrically constituted The particles of opposite sign are called electrons and protons and are joined by lines of force, which represent something going on in the ether, all electrical phenomena can be expressed in terms of these lines of force Lines of force represent a state of the connecting medium which unites electrons and protons and causes their apparent attraction Similar lines account for cohesion. Gravitational lines of force unite earth and moon We should always look for a medium, and we always find the ether operative in the physical universe; whether it is active in the mental universe we are not so sure Mind usually acts on mind through a physiological mechanism, whether such indirect mode of connexion is always necessary is a subject for investigation. The laws of mental action may be quite different from physical laws, we should not let mechanism dominate us, for we may have to enlarge our conceptions.

"THE Mountain Structure and Geographical Relations of South-eastern Asia" formed the subject of a discourse delivered at the Royal Institution on Friday, January 30, by Prof John W. Gregory. Prof. Gregory stated that the continuity of the Alpine-Himalayan system has been proved from western Europe to eastern India. Its further eastward continuation, according to one view, is across central China to Bering Straits, and according to another through western Burma to Sumatra and thence along

the southern islands of the Eastern Archipelago. Its diversion from its eastward course has been attributed to the mass of Chinese Tibet, the structure of which is complex, being due to movements at two different dates. The later movements belong to the series which made the Alps and Himalaya and are geologically modern The other group is much older and is represented in Asia by the Altaid mountains. The most direct proof of the Himalayan movements is afforded where rocks which, as in the salt basin of Yunnan, were not in existence when the Altaid mountains were made have been intensely folded. At the end of the Altaid uplifts, the site of the Indian Ocean was covered by Gondwanaland, which extended from South America across the Old World to Australia This continent was broken up by successive subsidences, and the gulfs thus formed gradually became the Atlantic and Indian Oceans These movements were accompanied by volcanic eruptions, which deluged equatorial Africa and western India under floods of lava, while East Africa was torn asunder by the formation of the Great Rift Valley One difficulty in the explanation of these eruptions and fractures by the foundering of the floor of the Indian Ocean was the apparent absence of any corresponding phenomena on its eastern side The evidence now shows that Burma and western China were disturbed by volcanic eruptions and fractures contemporary with those of East Africa The geographical relations of the mountains of south-eastern Asia therefore indicate that the Alpine-Himalayan system is part of a belt of crumpling of the crust where the in-sinking northern dome of the world pressed against the tropical and subtropical belt

AT a meeting of the Newcomen Society held on January 28 two historical papers were read, the first being by Mr Hamilton, an American member, on "The Windmills of Cape Cod," while the second was by Mr. David Brownlie, and was entitled "Some Notes on a Neglected Worthy, John Patison of Airdrie" John James Patison was born at Leith in April 1828 and died at Inverkeithing in July 1905. Though his youth was passed in a bookshop and a bank in Edinburgh, he was able to start a salt works at Musselburgh, and afterwards, when he had removed to Airdrie, he began experimenting on the carbonisation of shale, and near Airdrie he established the Whiterigg Chemical Works Mr Brownlie referred to him as one of the earliest practical workers in the commercial development of the Scotch shale oil industry, though its real founder was, of course, James Young The distillation of shale at Whiterigg ceased about 1864, a few years after the discovery of American petroleum Patison was also the inventor of an internal screw conveyer retort, and Mr Brownlie in his paper gives some interesting details of other inventors in the same field.

THE rainfall of 1924 is dealt with in the *Meteorological Magazine* for January, but at present it is only possible to outline the general features. Over the British Isles as a whole, the year was unusually wet; the average fall was 48·5 in., which is 117 per cent. of the normal. It was wetter than any year since 1903, when the rainfall over the British Isles was 52·5 in. or 127 per cent. of the normal. In 1924 the rainfall was only slightly heavier than in 1916 and 1912, when the percentage of the average was 115 and 116 respectively. In parts of Scotland and the north of England, there were fairly large areas where the 1924 rainfall was deficient, and at Louth in Lincolnshire the rain was only 89 per cent. of the average. In England and Wales the rainfall for the year was 121 per cent. of the average for the 35 years, 1881–1915, in Scotland it was 105 per cent., and in Ireland 122 per cent. More than 140 per cent. of the average occurred on Dartmoor, on the Cotswolds, and to the north of London at Maidenhead and Chelmsford At High Wycombe, in Buckinghamshire, rain measured 38·94 in, which is 13·04 in. more than the average, and is 50 per cent. above the normal; it is the largest fall, with the exception of that in 1903, since records were commenced in 1846 The London rainfall, according to the Camden Square records, was 33·08 in, which is 8·61 in or 35 per cent above the normal, the largest rainfall since 1916 Rain fell in London on 188 days, and the duration of rain for the year was 539 6 hours January, May, September, and December were all very wet, whilst February and March were unusually dry.

THE Hunterian oration in connexion with the Royal College of Surgeons of England will be delivered at the college on Saturday, February 14, at 4 o'clock, by Sir D'Arcy Power.

SIR WILLIAM B HARDY will deliver a lecture on "Problems presented by Films on Solid Surfaces," under the auspices of the Chemical Society, at 8 P.M. on Thursday, February 26, in the lecture hall of the Institution of Mechanical Engineers, Storey's Gate, Westminster, S W. Invitation has been extended to fellows of the Physical Society.

ON Tuesday, February 10, at 5 15 P M, Prof. J. Barcroft, Fullerian professor of physiology, begins a course of four lectures at the Royal Institution on the colour of the animal creation. The Friday evening discourse on February 13 will be delivered by Dr. B. Malinowski on the forces of law and order in a primitive community, and on February 20 by Prof T H. Pear on acquiring muscular skill

THE Minister of Agriculture and Fisheries has appointed a permanent committee to advise the Ministry on all questions relating to agricultural meteorology. The committee consists of:—Sir Napier Shaw (Chairman), Prof. V. H. Blackman, Mr H. Corless, Mr. R A Fisher, Mr. J. C. F. Frver, Mr. R. H. Hooker, Mr. R. G. K Lempfert, Sir Thomas Middleton, Mr. J. Ramsay, Mr. H G. Richardson; Mr. W. R. Black, of the Ministry of Agriculture, has been appointed secretary of the committee.

AT the annual council meeting of the National Union of Scientific Workers, which was held at the University of London Club on January 31, the president, Prof. G. H. Hardy, announced that the efforts which the Union has been making for some

time past to obtain an increase in the Treasury grant to the Royal Society, in aid of scientific publications, have been successful. It is understood that, in the estimates for the coming financial year, the Government will make provision for an increase in this grant from 1000*l.* to 2500*l.* a year. The Annual Report of the Executive Committee records many other activities of the Union which are of interest and benefit, not only to members, but also to the scientific world at large. During the past year, three new branches have been formed, and the number of new members elected has been considerably larger than in previous years.

LAST month Mr A Cobham made a flight over the Himalayas The *Times* gives some details of his journey. Leaving Calcutta he reached Jalpaiguri in 3½ hours, the object of this part of the journey being to survey an air route to Darjeeling. From Jalpaiguri he started his reconnaissance over the Himalayas, passing over Darjeeling at a height of some 9000 ft Flying towards Kinchinjunga, Mr. Cobham experienced difficulties at about 12,000 ft., but after turning and descending, he returned and climbed without difficulty to 17,000 ft. At that altitude breathing was not easy, but temperature was not so low as at 12,000 ft After taking a series of photographs of the range, Mr. Cobham returned to Jalpaiguri, having occupied only 3½ hours in his flight He believes that the whole Himalayan range could be accurately surveyed from the air at a relatively small cost, and that a flight over Mount Everest would be easy

THE arrears due to the War in the great *Index Kewensis* are being rapidly overtaken. The last pre-War Supplement, covering the years 1906–10, was published in 1913, and it was not until nine years later that it was possible to issue Supplement V., covering the years 1911–15. But Supplement VI., covering the years 1916–20, is now complete, and printing has begun at the Oxford University Press We learn from the publishers that their stock shows that a large number of sets of the work have not yet been completed to date by the addition of Supplement V. (published in 1921), and they ask us to direct the attention of librarians to this fact. The value of the work, both scientific and pecuniary, is, of course, seriously impaired by the failure to complete sets; and the relatively low price at which the Supplements are issued has been made possible by the support given by librarians and learned institutions all over the world.

INTERMITTENT bournes are flowing in chalk areas in the south-east of England, and the Croydon bourne is no exception. It is probably not yet at its highest, but broke out as usual in the garden of the Rose and Crown, at Warlingham It is now gradually creeping up the valley. More interesting is the fact that the Addington-Wickham Bourne is again out This, after disappearing for about 33 years as a flow of any magnitude, appeared in June 1916, and is now again flowing, but it has passed its maximum The gravel-pit which has been made in its path was covered by water, but not to any depth, and it is subsiding. This bourne is not directly on the chalk, but wells up through a thickness of tertiaries, and hence does not appear until these have been saturated It is noteworthy as being in the valley which must have been at one time an upper reach of the Ravensbourne. Sodden patches which have been let down near its source seem to show that underground solution is taking place to some extent

Our Astronomical Column.

THE OPPOSITION OF EROS IN 1931.—This opposition will be much the most favourable since Eros was discovered in 1898. Dr. Witt, who discovered the planet, has been engaged on the study of its perturbations up to 1931, and announces that he has now completed this work. The German observatories are now making arrangements for the careful observation of stars that lie near the planet's track, as they will be required as reference stars; they are also inviting co-operation in other countries.

The details of Dr. Witt's work are not yet published, but the following ephemeris, based on earlier elements, gives a general idea of the conditions during the time that the planet is within 19 million miles of the earth.

		R.A.	Decl.	log Δ.

	,, 22	9 35	20 10 S.	9·307

The maximum parallax, on Jan. 29, is about 52″.

Longer preparation is possible on this occasion than at the 1901 approach, and the minimum distance is little more than half so great; thus we may hope for a corresponding increase in accuracy

THE U.S.A. NAVAL OBSERVATORY, WASHINGTON.—The report of the superintendent, Capt E T Pollock, for the year ended June 30, 1924, has been published. In the Nautical Almanac Department, special investigations have been made of the orbits of the satellites of Saturn and Neptune. In the latter 1633 observations, ranging from 1889 to 1923, are included. A new catalogue of 1504 standard stars has been constructed and half of it is in type The positions of the stars are a decided improvement on those in Boss's General Catalogue. Most of the Nautical Almanac for 1927 is in type

The details are given of work with two transit circles and several equatorials, with these last, satellites and minor planets were observed. There were two dates when the sunspot activity showed a minimum, February 1923 and the end of August 1923. Numerous observations were made with the Prime Vertical Instrument: three determinations of the constant of aberration from these observations are 20·54″, 20·55″, 20 58″. All appear to be on the large side.

The Department for Training Naval Officers includes branches for studying the gyro-compass and the magnetic compass.

Research Items.

PRIMITIVE MURAL DECORATION IN SOUTHERN INDIA.—A paper by the late Dr Nelson Annandale, published in vol viii No. 4 of the Memoirs of the Asiatic Society of Bengal, describes a primitive but effective form of art which is found in a Uriya village on Samal Island on the northern shore of Lake Chilka in Orissa The people of Samal speak the Uriya language, but physically they are a mixed type, some showing traces of aboriginal blood while others present a Mongoloid appearance Their culture is primitive and nominally they are Vishnuvite Hindus mostly of the Goala or cowherd caste Some of the houses are composite, sheltering several families under one roof The walls of the houses are uniformly covered with a wash of red earth forming the background of the decorations The simplest form of pattern is made by applying the three fingers dipped in chalk and water to the walls The more elaborate patterns fall into two groups, of which the character is indicated by their names One is called *janar*, a kind of maize, the other *punjha pareda*, "four coconuts," of which, however, only three can be distinguished as a rule. These patterns are usually executed by men More elaborate designs also are in use, some made by women, in which birds and fishes appear Most of the interior decorations were painted in several colours, while some of those used in internal passages were mythological Outside are certain lucky signs, such as double fish and footprints; the object of the decorations seems to be purely æsthetic.

ARCHÆOLOGICAL REMAINS IN NEW ZEALAND.—In vol ii No 4 of the Records of the Canterbury Museum, Mr H. D. Skinner continues his description of the objects found in caves near Christchurch, N Z., opened in 1889, which were sent to the Otago University Museum in 1922 The material from Monck's Cave, which is situated about a mile east of the Moa-bone Point Cave previously described, although more interesting than that found in the latter, is scientifically of less value, as no record was kept of its stratification. Sixteen pieces of moa bone were sent to the Museum, eight of which were worked. One of the most interesting articles found was a carved bailer, the only known example from South Island, which, with a paddle, was found immediately the cave was opened. It is therefore probably of later date than the moa-hunter age Its decorative *motif* of a bird's head and loop coils was not previously known from this district. An outrigger float is the only New Zealand example which has been preserved Of a number of adzes, several were Polynesian in form but none of West Pacific types. Among a variety of other articles were a toy canoe and paddle and a toy dog, which confirms the accounts of Maori dogs given by early travellers. One of the most interesting discoveries was a series of cuttings of human hair showing a considerable variation in pigmentation, ranging from dark brown to chestnut. Its very fine plaiting points to Polynesian relationship.

COLOUR FATIGUE IN THE EYE.—In a pamphlet (reprinted from *The Medical World*) Dr. F. W. Edridge-Green, who is special examiner and adviser to the Board of Trade on colour vision and eyesight, quotes the following passage from Dr. Troland on minuthesis (that is, colour fatigue): "The general conclusion to be drawn from the work is, therefore, that minuthesis due to one colour does not alter the luminosity of another colour to a degree differing appreciably from that in which it is altered itself. In other words, the change in sensitivity to brightness occasioned by stimulation of the retina is independent of the wave-length constitutions of the minuthetic and of the reacting lights. This seems to imply that the luminosity function is not essentially linked with the colour or chromatic function, and stands in contradiction to the views of Abney, Ives, and others, who treat luminosity as the sum of the primary colour values of any stimulus. The present results appear also to be in conflict with experimental data along similar lines published by Abney and by Burch, so that further study of the problem would seem to be required on a larger number of subjects." These conclusions are in agreement with those to which Dr. Edridge-Green himself and co-workers have come (see "Physiology of Vision," p 248, Proc. Roy. Soc., 1912).

LARVÆ OF DECAPOD CRUSTACEA.—Notwithstanding the strange forms they frequently assume, the larvæ of decapod Crustacea have in recent years received very little attention at the hands of zoologists. This is no doubt due to the great labour involved in linking up unknown forms with parents which often have a widely different appearance, and to a fear that, when all is done, little real advance will have been made in our knowledge of the group In his report on the larval decapods obtained by the British Antarctic (*Terra Nova*) Expedition (Crustacea, Part IX. British Museum (Natural History) 1924 Price 15s.) Mr Robert Gurney has shown that such studies may yield indications of great phylogenetic importance. Although the numbers of known larvæ are still few in comparison with adults, it is clear from Mr Gurney's work that a classification derived from them will sometimes diverge in a striking manner from the system generally adopted. This system, based mainly on the morphology of the adult decapod, is none too securely founded, and there is little doubt that a knowledge of the larval structure will be of great assistance in its revision Two of the more important conclusions that Mr. Gurney has reached are that the Stenopidea should be removed to the Reptantia, and that the Thalassinidea are not homogeneous, but fall into two divisions—a Homarine series, including the Axiidæ and Callianassinæ, and an Anomuran series, including the Laomediidæ and Upogebiinæ A feature that will appeal strongly to every student of the group is that in Mr Gurney's work he is provided, for the first time, with a systematic presentation of all available information on decapod larvæ Under most of the family headings the principal larval characteristics are summarised or discussed, and there is a valuable list of references to the widely scattered literature

THE TANNING QUALITIES OF MANGROVES.—In *Indian Forest Records*, vol. x. part x for 1924, Mr. J. A Pilgrim has an interesting account of the mangroves of Tenasserim as a possible source of supplies of tannin. The writer was appointed tannin expert to the Government of India with the idea of surveying from this point of view the mangroves of Burma, but as delay was caused in this project through the War, he has in the meanwhile carried out an investigation of the mangroves of the Sundarbans of Bengal, and thus is able to compare his Burmese results with further data obtained in more northern latitudes. Pilgrim points out that whilst on the whole the mangroves of the Sundarbans and of Tenasserim show no noteworthy differences, yet on the whole, (1) the best of all the mangrove tans, and (2) the commonest of these tans, both show themselves richer in tannin in the more southern

latitude. The best source of tannin is said to be *Carapa moluccensis*, the commonest *Rhizophora mucronata*. This latter species has been widely collected, and Pilgrim points out that it has shown itself richer in Borneo than in the Philippines, whilst chemists in Sarawak, S. Borneo, get somewhat higher yields of tannin than Pilgrim from N Borneo, and now the Burma material proves more valuable than that from Bengal The writer concludes that his present results seem to support the general thesis that mangroves increase in tannin content as they approach the Equator.

OVERSEAS TRANSPORT OF APPLES.—Early in 1923 a scientific expedition, consisting of Dr Ezer Griffiths, Mr. A. J Smith, and Mr Edgar A. Griffiths, was sent by the Food Investigation Board to study problems involved in the transport of apples from Australia to England. Special Report No. 20 of the Board, entitled, "The Problems of Apple Transport Overseas," by Drs Kidd and West (H M S O, price 9*d* net), is a general survey and summary of the results obtained. The investigation originated in an inquiry as to whether the disease known as "brown heart" could be correlated with the atmospheric conditions in the holds in which the apples were carried Four boats, representative of the different systems of marine refrigeration in use, were studied and a complete record obtained of the carbon dioxide content of the atmosphere of the holds, and of the temperature distribution in the interior of the cargo of apples One surprising result observed was the magnitude of the accidental ventilation which takes place due to leakage; calculations based on the estimated rate of production of carbon dioxide by the respiration processes of the apples and the periodic measurement of the amount of gas present in the hold show that, in one of the boats studied, about 300 cubic feet of air per day per ton of apples finds its way into the hold. This was the case of a boat equipped with forced circulation of the cooled air In a boat depending on convection currents from cold brine pipes for the cooling effect, the leakage was considerably less and the accidental ventilation was only just sufficient to keep the carbon dioxide concentration below the danger limit of about 10 per cent. Another important result of the expedition was to show that none of the present systems employed for the stowage of the apple cases produced a uniform temperature distribution throughout the mass This is a problem which is now being studied at the National Physical Laboratory by the aid of scale models. The expedition also afforded an opportunity for observing under marine conditions the behaviour of various types of physical apparatus used in the investigation, such as electrical thermometers, carbon dioxide indicators, hygrometers, and anemometers

PETROLEUM IN THE LOST SOLDIER-FERRIS DISTRICT, WYOMING.—Messrs. A. E. Fath and G. F. Moulton, of the United States Geological Survey, have recently completed their work in this interesting area of south central Wyoming, an area in which there has been active oilfield development since 1916. The results of the survey are contained in Bulletin 756. The geology conforms with that characteristic of the Big Horn Basin as a whole, and, as would be expected, Cretaceous beds constitute the most important stratigraphical and economic formations. In this area of about 600 square miles, the authors have described nine domes and anticlinal folds with which oil and gas are associated; these local structures, regarded as being post-Oligocene in age, are superimposed on what is known as the Rawlins Uplift, a regional structure of early Tertiary or even older achievement. Some difficulty was experienced in mapping the district owing to the outcropping formations being much concealed by alluvial wash and blown sand, but two of the domes, Lost Soldier and Bunker Hill, are indicated topographically, especially the first, which accounts for its earlier development as an oilfield. Faulting has affected the structures considerably, most dislocations cutting across the flanks of the folds; this naturally has a marked influence on the distribution of the oil-sands involved. In 1921 the Lost Soldier field produced 380,811 barrels of oil from 28 wells, in the same year the Ferris Dome produced 16,740 barrels, and what is known as the "G.P. Dome" yielded 74,199 barrels from 3 wells On another, the Mahoney Dome, a rich gas sand was encountered with an open-flow yield estimated at 50,000,000 cubic feet of gas per day, lightning ignited the gas and the well burned for 27 days before being extinguished, which was accomplished by exploding a 25-pound charge of dynamite close to the well-mouth, taking advantage of the momentary slowing down of the gas flow and then snuffing with steam These and other significant facts indicate that the area has decided commercial possibilities, though accessibility and questions of transport and marketing of the oil are problems which apparently are only just being solved

WIND DIRECTION, CLOUD AND VISIBILITY.—The Meteorological Office, Air Ministry, in Professional Notes, Vol 3, No 36, gives a discussion "On the inter relation of wind direction with cloud amount and visibility at Cahirciveen, Co Kerry," by Mr. L. H. G. Dines and Mr P I Mulholland The object is to ascertain whether there is a statistical relation of sufficient magnitude to aid in forecasting the amount of cloud and visibility at night from observations in the afternoon and evening The data for cloud cover a period of ten years from 1911 to 1920 South winds are the most common, followed by south-west and west The outstanding feature is the excessive amount of cloud with south winds in each season and at different hours of the day The clearest skies occur with calms in spring and north-east winds in winter and autumn, a clear sky may be expected, with either, once in 5 or 6 times on the whole, as against once in 77 for south-west winds. For the inter-relation of wind direction and visibility the data employed are for about two years, 1919 and 1920 As a rule, visibility at Cahirciveen is good, the best occurring with northerly winds, the poorest with southerly, the latter being due to the generally damp conditions prevailing with such winds The authors deal with the Beaufort letter "v," *unusual visibility*, as a sign of coming rain, and so far as Valencia Observatory is concerned, observations there do not support the old theory. Much more proof than observations at this special observatory will be required substantially to disprove its general applicability As a standard for normal humidity, the observations for 1886–1910 are used, it must not be overlooked that a good many years ago the position of Valencia Observatory was shifted from an island to the mainland.

METAL CLAD ENCLOSURE OF CONDUCTORS.—The tendency of modern electrical engineering is to devise automatic operation to replace manual operation, and so provide "mistake-proof" plant. As the voltages of transmission, owing to the large amounts of power that have to be transported, are continually being raised, it is necessary also to devise methods of making contact with a "live" conductor a practical

impossibility. Mr. H. W. Clothier, in a paper read to the Institution of Electrical Engineers on January 22, gives a very able discussion of these and similar problems. He points out that the ideal arrangement is to enclose metallically every conductor so that it is completely inaccessible when alive These metallic covers are connected with the earth, and if they be used over the whole supply system from the generators to the load, they provide practical immunity from burns and shocks. If this method is carried to its logical conclusion, overhead lines would have to be replaced by underground cables. The initial cost, however, of high-tension underground cables is at present in most cases prohibitive, and so compromises have to be arranged It is also of importance that faults occurring in a transmission system should be rapidly cleared, as in several cases high-frequency currents are set up in the system, and these produce very serious electromagnetic interference with neighbouring telephone and telegraph lines Shocks and fires from this form of interference are an appreciable "risk," and have to be taken into account The author concludes that, for safety of the operators and continuity of the supply, the use of universal metal-clad enclosure is highly desirable There should always be a stable neutral point on the network maintained at earth potential, and all operating mechanisms should be thoroughly trustworthy and be periodically inspected.

THE POLYMORPHIC FORMS OF IRON.—The issue of December 5, 1924, of *Die Naturwissenschaften* contains an interesting summary by F Wever on the physics of the technical varieties of iron. The remarkable variation of properties of this material which makes it so valuable a substance depends essentially on the fact that iron can be obtained in several polymorphic forms, the behaviour of which towards carbon, which invariably accompanies such iron, is very different The author reviews the properties of the polymorphic forms of pure iron, of which there are four, namely, α, β, γ, δ. The lattice forms of α-, β-, and δ-irons are the same and are those of a body-centred cube, while that of γ-iron is a face-centred cube. The maximum solubility for carbon is possessed by γ-iron and corresponds to 1·8 per cent. at 1140° δ-iron, which only exists between 1535° and 1410°, can dissolve 0·38 of carbon at the latter temperature In contrast with this the solubility of carbon in β- and α-iron is extremely small The properties of iron carbide and the relations between iron and carbon are discussed in the latter part of the paper, which concludes with a brief summary of the theory of hardening. The author favours the theory of Maurer, according to which carbon is in a condition of atomic dispersion in α-iron, the volume of which is thereby decidedly increased The condition of strain thus induced is regarded as the cause of the exceptional hardness of such steel.

THE SILICA OF PLANTS.—D. R. Nanji and W. S. Shaw have recently found (*Chemistry and Industry* Trans., Jan 2) that about 90 per cent. of the total silica occurring in plants is present as free silicic acid, probably in the colloidal state The remaining 10 per cent. is in a form from which it can only be extracted after preliminary treatment with acid, probably as an ester-like combination with a polysaccharide constituent of the plant.

THE IDENTITY OF GEBER.—E. J. Holmyard, in an article on the present position of the Geber problem in *Science Progress* for January 1925, considers it definitely established that Geber is Jābir ibn Hayyān. The Latin works ascribed to Geber are probably not literal translations from the Arabic, but are works based on Arabic knowledge. There is not sufficient evidence at present definitely to state that these Latin works are genuine. A study of the works of Jābir confirms his reputation as the greatest chemist of Islam.

THE ULTRA-CENTRIFUGE.—Svedberg and Rinde, in the Journal of the American Chemical Society for December 1924, describe a new instrument, the ultra-centrifuge, for the determination of the size and the distribution of size of particles in amicroscopic colloids It enables particles which are invisible in the ultra-microscope to be measured. The theory of the instrument is given in detail; measurements of the radius of the particles of gold sols (average radius 2·3-11·6 $\mu\mu$) made with this instrument give values 11-38 per cent. higher than those obtained by Zsigmondy's nuclear method The nature of the protective action of gelatin upon fine-grained gold sols is also studied, minimum and maximum values for the thickness of the gelatin layer adsorbed around the gold particles being obtained.

CRYSTAL FORMATION.—The development and formation of crystals is the subject of a paper by Dr. T. V Barker in *Chemistry and Industry* for January 16. Among the topics discussed are lattice structure; polymorphism and isomorphism, mixed crystals; chemistry of the crystalline condition The main lines of advance in the X-ray examination of crystals are outlined. The section on crystal mixtures is somewhat detailed. The equilibrium relations between a mixed crystal and its mother liquor are most simply illustrated by leaving out of account the variable amount of water (or other solvent) requisite for solution, and then plotting percentage composition by weight of the two constituents of the mixed crystal against their relative proportions in the solution Two types can then be distinguished, the first of which is illustrated by mixtures of cobalt and ferrous sulphates, and the second by mixtures of potassium permanganate and perchlorate (Muthmann and Kuntze). The complete equilibrium diagram of ferrous and magnesium sulphate mixtures is given for the first time; the system belongs to the second type.

LOW TEMPERATURE TREATMENT OF BITUMINOUS MATERIALS.—T. W. S Hutchins, at a joint meeting of the Chemical Engineering Group and the London Section of the Society of Chemical Industry on January 16, gave an account of the low temperature treatment of bituminous materials. He set out by cataloguing the conditions which must necessarily be fulfilled if such a process is to be technically successful. It would seem that these conditions are extremely stringent, for the number of such "points" (in the Wilsonian sense) reached twenty-two. He described the development of the "fusion" retort and its construction as at present used It consists of a horizontal, revolving, externally heated retort through which the comminuted material passes. The retort contains a series of paddles on a free horizontal shaft, so that when the retort revolves, these paddles roll over in such a way as to churn up the charge, facilitating the escape of vapours and at the same time preventing the growth of accretions on the walls of the retort. It would seem that the plant is designed primarily for the recovery of liquid distillation products, and the yields obtained from a number of bituminous materials are given, but without data to indicate how far the processes are commercially successful.

Scientific Work of the Fishery Board for Scotland.[1]

AMONGST the points of scientific interest in the report for 1923 of the Fishery Board for Scotland are the facts pertaining to the continued abundance of all kinds of fishes, swarms of small haddocks especially being noted Thus the total capture was little short of that in 1919, though exceeded by that in 1920 when the rush of boats was at its height. Herrings show no sign of diminution even under the unfavourable conditions of capture, the returns much exceeding those of the previous year, and almost reaching those of 1913

The work of the scientific staff includes a paper of special interest by H. Thompson on "Problems in Haddock Biology," which has already been noticed in NATURE (August 30, p 333).

Alex. Bowman treats of Arnoglossus and especially of what he thinks a post-larval *A. imperialis* (with a coloured figure). He remarks that *A. laterna* has a similar distribution to the sole (*Solea vulgaris*), and asks what are the factors which have prevented its establishment on the East Coast of Scotland by Nature or by transplantation. The sole has always, however, occurred sparingly on the East Coast in such bays as St. Andrews, and the transplantation of about 600 from Scarborough to this bay has had little effect on its abundance. He points out that other species of Arnoglossus enter by the Strait of Dover and reach the Skager Rack and the Cattegat, whereas he thinks *A imperialis* must have reached the northern North Sea (where 3 young specimens were found) from the Atlantic, and that they do not survive. Possibly investigations both of the life-histories of the several species and of the various currents may afford further information. The efforts by the same author to locate the areas in which the herring spawn by the capture of what he terms "spawny" haddocks which "are well fed and plump of form, and have a characteristic bloom on the epiderm which masks the black pigment," seems to be somewhat far-fetched, for, whilst no less than 80 boxes of large haddocks may be caught where the herrings spawn, no more "bloom" occurs on those with their stomachs full of ova than on those caught by the liners on other grounds. Again the cod, which feeds on the ova of the herring no less greedily than the haddock and even scoops up quantities of gravel with this food, presents no external change. No doubt such investigations are useful on unknown ground—though the external changes are more or less imaginary.

In a careful contribution on the use of the Petersen grab, A. C. Stephen perhaps makes too much of this instrument, which, though a useful adjunct to other methods of ascertaining the fauna of the sea-bottom, such as the dredge and the trawl, falls far short of the revelation a single storm will disclose on the beach. Not all the elaborate calculations of this and that species per square yard brought up by the grab will add more to our knowledge than the storm. It is curious that neither Pecten nor Nephrops (the rich food of the cod) seems to have come in the way of this instrument in the area of the Firth of Forth.

An interesting digest of the summer herring fishery of 1922 is made by H. Wood, whose observations and the accompanying map point to the occurrence of shoals in the same areas from June to September, the shoals perhaps differing in their composition, but still affording good catches He found that the northern large herrings spawned before the southern, and he makes remarks on the spawning areas and the times of spawning, an intensive period being the end of August.

An elaborate and interesting paper is that by Prof. D'Arcy Thompson on the trawling statistics of Aberdeen from 1917 to 1921, in continuation of that issued in 1917, the period comprising two of the War years and three of unusual activity These statistics again emphasise the fact that the old East Coast fishing grounds are as productive as formerly, the value of the catches being more than doubled, and this in face of the usual pessimistic views of the sea-fisheries. Whilst the post-War catches were much above the average, it is noteworthy that in 1917 the captures of codlings rose considerably, indeed were greater than in any previous year, and continued at a high level until 1920 Cod were much in the same condition. Haddocks, which had been rather scarce in 1914 and 1915, went beyond pre-War levels in 1916 and continued to increase until 1919, the average per voyage being nearly four times that of 1913, and, though diminished in 1920 and 1921, were still above pre-War catches. The advocates for accumulation during the War would point to this as proof of their theory, but such irregularities have often occurred previously and will occur in the future

An important addition to the scientific equipment of the Fishery Board is the new Research Laboratory, a brick building of one story, with various rooms for the staff, besides a museum and library. It is within easy reach of the Bay of Nigg and Torry Harbour, Aberdeen. The Fishery Board apparently at present assumes responsibility for these researches, which do it credit, but perhaps in future it would be well if, as in the case of the Royal Society, the caution were prefixed that the Board does not accept responsibility for the views of the authors W. C. MCINTOSH.

[1] Forty-second Annual Report, Fishery Board for Scotland, being for the year 1923. (Edinburgh: H.M. Stationery Office, 1924.)

Science and the Instrument Industry.[1]

THE British Scientific Instrument Research Association is fortunate in that most of its members are, by the nature of their work, in constant contact with research, and consequently in a position to know what it implies, and understand its methods and results. Many of these participating firms have, in fact, long been in the habit of carrying out original investigations in their own laboratories. They realise, therefore, the lines along which advance is possible and desirable, and, what is most important, they have had experience in formulating their problems in a scientific manner. On the other hand, the research staff of the Association has learnt to envisage the problems put before it from the manufacturer's point of view, and to adapt itself to practical needs and the limitations imposed by the necessity of economic production. The efficiency of this staff is very largely due to the good fortune of the Association in having as its director of research Sir Herbert Jackson, who is not only known for a variety of pioneer investigations in the realms of pure and applied science, but has also had a particularly wide experience of matters concerning instrument design, and of the psychology of the manufacturer. The Association is largely a body of his shaping, and he has made it a scientific instrument for the setting and solving of problems fundamental for the industry concerned.

The sixth annual report of the Association has just

[1] The Sixth Annual Report of the British Scientific Instrument Research Association, for the Year 1923-24. (London: 26 Russell Square, W.C.1.)

appeared At the end of it will be found a list of twenty-nine research reports which have been issued to members, to whom, of course, they are confidential. This is necessary to protect the participating firms against both foreign competitors and those British firms, fortunately few, which have elected to remain outside Very fittingly, both on account of the intrinsic importance of the subject to the instrument industry, and because the director is the leading authority on the chemistry of glass in Great Britain, a large number of these reports deal with problems concerning optical glass, such as the production of special glasses, including one asked for by the Admiralty, the preparation of neutral and coloured glasses, and the stabilising of polished glass surfaces, that is, the rendering of such surfaces immune from secular changes and the effects of climate This problem of stabilisation, and many of the other optical glass questions, are of particular importance to the fighting services, which depend so much on the use of optical instruments in a variety of conditions The fighting services are represented on the Council of the Association by representatives appointed by the Department of Scientific and Industrial Research, and their presence emphasises one of the services which the Association renders to the nation Evidence of the activity of the Association on the electrical side is offered by researches on magnetic properties of materials used for galvanometer suspended systems, and on certain X-ray problems

That the importance of the work done is realised by the Department of Scientific and Industrial Research, which controls the Research Associations, is indicated by the recent history of the Association, contained in the present report The Association has completed the first six years of its existence, and with them the period of its initial grant After investigations of the work of the Association by a special committee, including such experts as Sir Richard Glazebrook and Sir James Walker, the Department has resolved to offer an annual block grant of 10,000*l* on certain conditions which have been accepted, so that the Association has already entered upon its second grant period This period is characterised by certain administrative changes, among which the most important are those which bring the fighting services into closer touch with the Association, making them virtually members

The value of the Association to the instrument industry is not easily overestimated Apart from the actual researches which it carries out, it is often able to answer questions straightway from the knowledge which it has accumulated It acts as a centre of scientific activity, and has effectively introduced a spirit of co-operation among the participating firms, which is of the greatest promise for the future ability of the industry to excel foreign competitors The trust reposed in the director by all the members leads to a collaboration which would otherwise be quite impossible owing to trade rivalry, and there has already been an intercommunication of trade processes which has greatly benefited, for example, the various optical firms. Different firms, working in close touch with the research staff, have carried out in their own works and laboratories particular researches for which they have special facilities, and the results have been freely put at the disposal of all members This policy has already led to the production of certain instruments equalling, if not surpassing, those put on the market by foreign firms which, before the War, were supposed to be unapproachable

Between the National Physical Laboratory and the Association there exists a goodwill which is evidenced by the collaboration which has already taken place over the question of testing lenses by the Twyman interferometer and over certain other problems, such as the production of resistance wire. The Laboratory has always been a source of strength to the instrument maker in a variety of ways, but in the Association he has an engine which enables him to help himself in a way which no outside body can do Round the council table and in the sub-committees the members can thrash out questions both of technical design and of policy, avoid duplications of effort, and hear from one another and from outside members practical criticism and practicable suggestions, while the work of the research staff not only solves individual problems but also keeps constantly before them the high ideal of producing instruments not as good as, but better than, any yet on the market

The Botanic Garden, Copenhagen.

PROF OSTENFELD has prepared as a jubilee publication an account, referred to below,[1] of the history and resources of the Botanic Garden at Copenhagen. The contents of the work include many details of historical interest, while the botanist looking around for a continental school of botany will find much useful information in its pages

The Botanic Garden, now fifty years old, is the successor of one that, dating back to the close of the eighteenth century, had become inadequate Until 1871 the site was part of the old fortifications of the city, but by 1874 about twenty-four acres were transformed The old moat, rounded off, still exists as a lake, the view-point from which one sees the features of the garden extending in pleasant vistas up the rising ground on every side. Here the stately greenhouses, there the rock-garden, and in the background one or other of the scientific and public buildings which adjoin the garden. In recent years the trees have been collected into a special arboretum at Sorö, thus allowing space for a considerable extension of the rock-garden, and for special sections. Thus in the "Danish quarter" miniature chalk cliffs harbour the plants of Möen, and on other rocks and soils the native Danish plants are seen in their normal environment

The biological section is occupied by typical growth-forms such as might be expected in the home of Eugene Warming. The extensive glass-houses, in a compact block of more than 2000 square metres, include the higher palm-houses and lower ranges where tropical plants, orchids, aquatics, and other groups are housed. The more noteworthy plants, indoor and outdoor, are illustrated in the jubilee volume from photographs. The botanical museum shelters a mass of material, including special Danish, Arctic, and West Indian collections. The list of herbaria, more than two pages, is useful for any proposing to utilise them. The library of 25,000 volumes has been enriched by numerous donations. The Botanical Laboratory, dating from 1890, is a spacious block which is illustrated by a plan and photographs.

This home of Danish botany has been directed during the past fifty years by Joh Lange, F. Didrichsen, E. Warming (1885–1911), and C Raunkiaer, who was succeeded last year by C. Hansen Ostenfeld. The lists of staff include W. Johannsen, L Kolderup Rosenvinge, F Borgesen, and many others whose work has enriched the literature of botany Copenhagen has many advantages as a centre for the study of northern floras, and this memoir will prove a useful source of reference.

[1] "Botanisk Have gennem 50 Aar, 1874–1924." By C. Hansen Ostenfeld. Pp. 101. (København: G.E.C. Gads Forlag, 1924.) n.p.

University and Educational Intelligence.

CAMBRIDGE.—J. T. Irving, Gonville and Caius College, has been elected to the Benn W Levy Research Studentship in Biochemistry

The Governing Body of Emmanuel College offer to a research student, who is a candidate for the Ph.D. degree, a studentship of the value of 150*l* a year for two years Application should be made to the Master of Emmanuel College not later than July 31.

DUBLIN.—The Regius professor of physic in Trinity College, Dr John Mallet Purser, has made a gift of 10,000*l*, for the benefit of the Schools of Physic and Experimental and Natural Science, to be administered by a committee consisting of Prof J Joly, Prof A. F. Dixon and Prof W E Thrift The Board of Trinity College, in gratefully accepting this most generous gift, has expressed to Prof. Purser its desire that he should associate himself with the committee in the administration of the fund Prof. Purser has been connected with the teaching staff of Trinity College, Dublin, for 28 years, and during that period he has been to staff and students alike a source of inspiration and help, in the same way that Sir William Osler was to the scientific and medical schools at Oxford Prof Purser's many friends and pupils, not in Ireland alone, but in all parts of the world, will express the hope that he may long continue to hold his high position, and that he may still for many years to come preside over the School of Physic in the University to the service of which his life has been devoted.

LONDON.—A bequest of 5000*l*, subject to certain life interests, under the will of the late Mr. Arthur Jubber, has been accepted, the interest thereon to be used for scholarships, prizes, or lectures in any advanced subject, especially chemistry, botany, mathematics, ancient, modern, and natural history

The recognition of the London School of Economics as a School of the University in the Faculty of Arts has been extended to include the subjects of history and anthropology

The income of the Laura Soames Trust Fund for Phonetics is to be used for an annual prize in that subject.

The degree of D.Sc. (*Chemistry*) has been conferred on Mr. George Dean (West Ham Municipal College) for a thesis entitled "The Atomic Weights of Carbon and Silver."

The election of examiners for the matriculation examination for 1926 in the subjects of ancient history, botany, geography, geometrical and mechanical drawing, German, Greek, and modern history will shortly take place The necessary application form and particulars of the duties and remuneration of the office may be obtained from the External Registrar of the University, South Kensington, S.W.7 The completed form must be sent to reach the External Registrar by Monday, February 23, at latest.

MANCHESTER.—The Council has received from the General Electric Company of the U.S A the gift of an X-ray spectra apparatus for use in the Department of Physics

The following appointments have been made:—Mr. B. A McSwiney to be tutor and secretary to the Faculty of Medicine, Mr. B. Thomsett, assistant lecturer in electrical engineering in the Faculty of Technology; Mr. H. E. Martin, Whitworth meteorological observer.

The following resignations have been accepted:—Mr. H. Lowery, of the Department of Physics, on his appointment to a lectureship in the Technical College, Bradford; Mr. Ferris Neave, research assistant in entomology, on his appointment to a lectureship in the University of Manitoba.

OXFORD.—As was generally expected in the University, the vacancy in the Wardenship of New College has been filled by the election of the Right Hon H A L Fisher, member of Parliament for the Combined English Universities, and formerly president of the Board of Education As a Wykehamist in the fullest sense, Mr Fisher is certain to enter upon his duties as Warden of Wykeham's Oxford college with understanding and sympathy; while his distinguished career as an educational and administrative authority justifies the confidence which is widely felt in his ability to deal with the large questions of policy at present affecting the whole University There is every reason to believe that Mr Fisher, although his work as a writer and teacher has mainly lain in the department of modern history, will make his influence felt in the promotion of the best interests of natural science.

SIR AUBREY SYMONDS, second secretary of the Ministry of Health, has been appointed permanent secretary of the Board of Education, in succession to Sir Amherst Selby-Bigge, Bart

THE annual distribution of prizes and certificates at the Sir John Cass Technical Institute, Aldgate, London, E C 3, will take place on Tuesday, February 10. The awards will be distributed by Mr Sydney O Nevile, past-president of the Institute of Brewing, who will afterwards deliver an address on "The Fermentation Industries."

IN conjunction with the Development Commission the Departments of Agriculture for England and Wales and Scotland have instituted a new class of scholarships with the object of training those who desire eventually to take up posts as agricultural organisers or lecturers The scholarships are of two years duration, the first of which will be spent on investigational work in Great Britain and the second abroad The scholarship allowance in the first year will normally be 200*l*, the allowance in the second year will include provision for extra cost of travel and other expenses abroad The Development Commissioners have approved of the following awards—the first under this scheme H D Bennett (University College, Reading), F H Garner (University of Cambridge), V. Liversage (Harper Adams Agricultural College), T. Lewis (University College of North Wales), and A D Imper (Marischal College, Aberdeen)

FROM the Imperial College of Tropical Agriculture we have received a copy of its first detailed prospectus. The College, opened two years ago, trains students intending to become tropical planters, agricultural administrators or officers, or specialists, and offers facilities for study to graduates of other institutions. An important feature of the College is the provision for research and investigation which is afforded by its laboratories and fields, situated at St Augustine, seven miles from Port-of-Spain in the Island of Trinidad There are seven professors—of zoology and entomology, mycology and bacteriology, botany and genetics, chemistry and soil science, agriculture, economics, and sugar technology, and four lecturers, including one in veterinary science The ordinary diploma course covers three years. Fourth year courses are provided for specialisation in branches of agricultural science or chemical technology, in particular, sugar technology, and short (one-year) self-contained courses are also provided The College is at present non-residential.

Early Science at Oxford.

February 8, 1683–4.—Mr. Desmasters gave us a farther account of ye expansion of Ice He told us, that whereas the water he made use of lately (in some experiments of this kind, mention'd in the preceeding Minutes) was a sort of rough pump-water, which he has found turn milky and turbid immediately upon ye affusion of oyl of tartar *per Deliquium*, and considering also, that ye Ice made of this Water was a sort of rarified white Ice, he was hereby inclined to try, whether River water (which would readily mix with oyl of Tartar, without ye least precipitation) would, upon freezing, be expanded to ye height of ye pump-water above mentioned In order whereunto, he fill'd a glass tube of almost an inch diameter, with river water, to ye height of 6 inches (as he had done in ye former triall,) and then putting it to freeze in a mixture of snow, and salt, it gained but $\frac{1}{8}$ of an inch, after it was frozen, whereas ye pump-water got $\frac{3}{8}$ of an inch.

Dr Plot shew'd us some *Rosemary balls*, which are of ye nature of Mr Lister's Rust-balls, and were dug in Staffordshire, where they lye in lumps, in some of their Marl-pits Part of this stone apply'd to ye Magnet, after an hour's calcination.

A letter from my Lord Bishop of Ferns and Leighlin, mentioned a discourse of his Lordship's, preliminary to ye Doctrine of Sounds included in his letter. We received also a discourse from Mr. William Molyneux, concerning an optical Problem, which was read, and transmitted to ye Royal Society; Mr Bernard is desired to peruse, and consider it, as soon as it shall be returned from ye Royal Society, and give his thoughts of it to ye company.

February 9, 1685–6.—An Abstract of ye book of Fishes composed by Mr. Willoughby and Mr. Ray, printed by ye Royal Society, was read —Mr Cole of Bristol communicated an account of his observations on ye Purple Fish, for which the thanks of the Society were ordered.

February 10, 1684–5.—A Letter from Mr. Aston, dated Feb 2, was read It affirm'd (among other things) *That mortar is always without hair*; of ye truth of which we must own our selves not as yet satisfied.

Ordered—That Mr. Maunders, chaplain to Col. Luttrel, in Dorsetshire, Mr. Thomas, minister of Chard, and Dr. Turbervile of Salisbury, be asked what information they can give of ye late cold wind, which proved so fatal in Wiltshire, and Dorsetshire, about last Christmas Also that Mr Maunders be desired, as his occasions will give him leave, to draw up, and send us, an account of ye *Laver*, an Herb growing on ye rocks near Dunster Castle

An account of ye weather here at Oxford, December, January, and February last, taken by Mr. Walker, was by him presented to ye Society.

A letter from Mr Cuningham, dated St Leonards College, Jan 17, 1684–5, written to Mr. President, was read, It shewed his great readiness to procure us correspondents in Scotland; and contained a letter from ye reverend Dr. Skene, Provost of our holy Saviour's College, in St. Andrewes, to Mr. President, concerning ye establishing a Communication of matters Philosophicall, between this Society and ye learned Doctor, and his friends. It was ordered, that some of our Minutes be transcribed, to be sent ye Doctor, with the humble thanks of this Society for his compliance in this matter.

Mr. Standard of Merton communicated the results of his experiments on the weights of the several parts of Hens' eggs, weighed before and after boiling. The weighings were made with a pair of scales which turned with half a grain.

Societies and Academies.

LONDON.

Royal Society, January 29.—P. M. S. **Blackett**: The ejection of protons from nitrogen nuclei, photographed by the Wilson method Photographs have been taken of more than 400,000 alpha-ray tracks in nitrogen, using an automatic form of the Wilson condensation apparatus. A source of thorium B + C_1 was used, giving a mixed beam of 8·6 and 5·0 cm. alpha particles Among the tracks were found many normal forks due to the elastic collisions between alpha particles and nitrogen nuclei. In addition, eight forks were found of a strikingly different type. These abnormal forks represent the ejection of protons from nitrogen nuclei. Each track branches into two arms, one of which clearly represents the track of the proton. Since there is only one other arm to represent the tracks of both the residual nucleus and the alpha particle itself, the two particles must be bound together after the collision. When, therefore, a proton is ejected from a nitrogen nucleus by a fast alpha particle, the alpha particle itself is captured by the residual nucleus, forming a new nucleus which should have a mass of 17 and an atomic number 8.—R E. **Gibbs**: The variation with temperature of the intensity of reflection of X-rays from quartz and its bearing on the crystal structure Whilst the space group to which quartz belongs is known, the positions of the atoms in the molecule remain undetermined. The oxygen atoms cannot lie in the same basal planes as do the silicon, but must interleave them at a distance *d*. Of all the four unknown parameters, the variation of *d* alone will affect the intensity of reflection from the basal plane Reflection intensities measured from 0° to 800° C show that marked changes occur for all the planes at the transition point.—R. W **Gurney**. (1) Ionisation by alpha particles in monatomic and diatomic gases In the monatomic gases — xenon, krypton, argon, neon, and helium—the amount of ionisation increases with increasing atomic number, a result to be expected from their decreasing ionisation-potentials. In the diatomic gases—hydrogen, oxygen, and nitrogen—ionisation is less than in any of the monatomic gases, in spite of the high value of the ionisation-potential of helium. The ratio of the ionisation in the gases to that in air varies with the velocity of the alpha particles. The question is discussed whether the value (33 volts) found by Geiger for the average expenditure of energy per pair of ions in air is applicable to ionisation near the end of the range (2) The stopping-power of gases for alpha particles of different velocities. Since the stopping-power of a substance varies with the velocity of the alpha particles traversing it, the value obtained for the stopping-power of a gas by a measurement made over the whole or a large part of the range, as has usually been done, is merely an average value. Small portions of the range are here selected, so that the relative stopping-power has been measured for alpha particles of high velocity, of low velocity, and of intermediate velocity, separately. The relative values of the atomic stopping-powers tend to converge at the end of the range.—W. E **Curtis**: The Fulcher hydrogen bands The Fulcher lines and Allen's additions to them have been examined with the view of finding a theoretical interpretation of them. The wave-numbers of two of the strongest lines require correction by about 0·5 cm.$^{-1}$. The differences are then sufficiently regular to provide a criterion for the genuineness of the extra lines, which are in the main confirmed. The arrangement is consistent

with the view that they originate from combinations of simultaneously occurring rotation and vibration changes. New values of the molecular moments of inertia concerned are obtained which probably refer to an "excited" molecule. The nuclear vibrations within the hydrogen molecule seem to be very nearly simple harmonic, which would account, in conjunction with the small moment of inertia, for the unique structure of the system as compared with other band systems. The two sets of Fulcher triplets apparently originate from two molecules essentially similar in structure.—W. L. **Webster**. The magnetic properties of iron crystals. The magnetic properties may be accounted for by the Weiss theory of molecular fields. The magnitude of the molecular field is found for two crystals, giving respectively 620 and 479 gauss. The magnitude of the component along any one of the crystal axes varies as $\cos^4(\psi)$, (ψ) being the angle between the axis and the direction of magnetisation. The molecular field is a stable property of the crystal, and is affected considerably by the presence of impurities.—A. E. **Ingham** and J. E. **Jones**. On the calculation of certain crystal potential constants and on the cubic crystal of least potential energy.—E. C. **Stoner** and L. H. **Martin**. The absorption of X-rays. Two beams, defined by two slit systems, one vertically above the other, are reflected by the same crystal into two ionisation chambers. The beams are first balanced. A sheet of the absorbing material is then placed in the path of the upper beam, and the beams rebalanced by moving a wedge of aluminium across the path of the lower beam. The well-known law $\tau/\rho = \text{const}.\ Z^4\lambda^3$ holds only on the long wave-length side, or sufficiently far away on the short wave-length side of the K absorption discontinuity. Neither the formula of de Broglie nor of Kramers gives correctly the variation of the magnitude of the K group with atomic numbers. Measurements on the absorption co-efficients of uranium on each side of the three L absorption discontinuities show that the number of electrons associated with the L_3 level equals the sum of the numbers associated with the L_1 and L_2 levels. This is in agreement with Dauvillier's result for gold.—F. H. **Schofield**. The thermal and electrical conductivities of some pure metals. The maximum temperature used was 700° C. The thermal conductivity of aluminium increases with rising temperature, that of nickel decreases at first, and then above 500° C. increases. Copper, magnesium, and zinc showed, on the whole, slight decreases of conductivity with temperature. The values of Lorenz's function for copper, magnesium, and zinc were practically constant at all temperatures, that for aluminium showed a rise with increasing temperature; that for nickel showed a rise to 300° C., above which temperature it remained nearly constant except for an abnormal value at 400° C.—M. de **Sélincourt**. On the effect of temperature on the anomalous reflection of silver. The existence of a well-defined band in the ultra-violet (about 40 Å. in width) at which the reflection co-efficient of silver is negligible, has been utilised to investigate the relation between the frequency of the free electrons which are responsible for the reflection and the mean distance between the particles of the metal. The point of minimum reflection has been determined by a photographic method at the four temperatures 183°, −79°, 16° and 150°; the band is displaced in the direction of decreasing wave-length as the temperature is lowered, and is at the same time rendered sharper and narrower.—T. L. **Ibbs**: Thermal diffusion measurements. Mixtures of each of the following pairs of gases were used: hydrogen and carbon-dioxide, hydrogen and nitrogen, nitrogen and carbon-dioxide, hydrogen and argon, helium and argon. The apparatus consists essentially of a small cold vessel maintained at uniform temperature, joined by a connecting tube to a larger vessel the temperature of which can be raised as required to about 300° C. Thermal diffusion produces a difference in the distribution of the components of the mixture on the hot and cold sides, and the resulting change in composition on the cold side is measured directly by means of a katharometer, the open cell of which forms part of the cold side. There is a general tendency for the gas with the heavier molecules to diffuse towards the cold side. The total separation is nearly proportional to $\log T_1/T_2$ (where T_1 is the absolute temperature of the hot side, and T_2 the absolute temperature of the cold) in all cases.

Optical Society, December 11.—J. **Guild**. (1) An equipment for visual spectro-photometry. The equipment for visual spectro-photometry designed by the author and installed in the Optics Division of the National Physical Laboratory. The basis of measurement is Talbot's law as applied to rotating sectors. By employing a series of sectors the whole range of effective transmission from 100 per cent. to 0·01 per cent. is covered by a series of fixed points, each of which corresponds to a transmission about 90 per cent. of the next higher, with only a few sectors none of which is below 1 per cent. in its effective transmission. The gaps between the fixed points are covered by photometric wedges calibrated in terms of the sector discs. The field of the instrument is of the Lummer-Brodhun contrast pattern. (2) Transformation of trichromatic mixture data. Algebraic methods of transforming colour mixture equations from one trichromatic system to another are described. Measurements made in terms of the arbitrary working primaries of any trichromatic colorimeter can be transformed into any system of standard primaries or vice versa, without auxiliary measurements other than can be made on the instrument itself used in the normal manner.—L. C. **Martin**. A simple microphotometer. The addition of a few auxiliary parts, including a photometric comparison cube, permits an ordinary microscope to be used for finding the average density over a very small area of a photographic plate by visual methods. The instrument is useful with spectrograms and star images.

January 15.—W. H. **Steavenson**. A peep into Sir William Herschel's workshop. See NATURE, July 5, 1924, p. 21.—P. P. **Schilovsky**. Slow speed precision training gear governed from a distance. The increase in precision in the training of telescopes, microscopes, etc., is possible only if an electrical device, controlled from a distant station, is applied to the moving parts. The angular velocity of the training motor must correspond with that of the handle of the manipulator. Standard motors in which the speed of rotation depends upon load and output cannot be used, the only system available is one where the manipulator can revolve the magnetic field of a motor's element in strict conformity with the speed and direction of a distant device at the governing station.

Aristotelian Society, January 5.—G. Dawes **Hicks**: The dynamic aspect of Nature. The view that "force," in the sense of strain or stress, is a subjective phenomenon is devoid of justification. As it is requisite to distinguish the *perception* of a colour from the *colour*, so it is requisite to distinguish the *perception* or *feeling* of a strain from the *strain* which

we perceive or feel. Though the sun is not *conscious* of a strain when it pulls the earth, it does not in the least follow that in doing so it is not subject to a strain. On the other hand, one may legitimately argue that the "mind" or "self" is as such neither subject to a strain, in the sense in which that term is used of material things, nor to be conceived as putting forth energy. In willing, as indeed in cognising, the "mind" is certainly active, but the activity is not analogous to what is signified by the phrase "exertion of force". Further, there is no ground for the contention that what we are cognisant of as "force" or "energy" is confined to organic phenomena, a supposition which would necessitate a theory of vitalism cruder than any hitherto suggested. The truth rather is that modern physics, with its conception of "lines of force" and its doctrine of energy, presupposes the reality of the factors of stress and strain in the physical world. The concept of either "force" or "energy" as an entity *per se* is doubtless a pseudo-concept, but the notion of mass and energy as inseparably combined would seem to be a necessity for physical theory. The attempt to conceive of energy as the one physical reality and of matter as a derivative therefrom results simply in the materialisation of energy. A quantum of energy becomes to all intents and purposes a materialised body, although matter is supposed to be dispensed with. The paper concluded by criticising certain consequences which have been thought to follow from the general theory of relativity.

Mineralogical Society, January 20.—K. **Yardley**. An X-ray examination of calcium formate. The orthorhombic bipyramidal unit cell contains 8 asymmetric molecules. The dimensions are $a = 10{\cdot}19$ Å., $b = 13{\cdot}41$ Å., $c = 6{\cdot}27$ Å. The structure is founded on the Bravais lattice Γ_0, and belongs to the space-group C_{2h}^5.—John **Parry** and F. E. **Wright**. Afwillite, a new hydrous calcium silicate from Dutoitspan mine, Kimberley, South Africa. This mineral was found by Mr. A. F. Williams as large water-clear crystals. These are monoclinic. Analyses give the formula $3CaO\ 2SiO_2\ 3H_2O$ or $2H_2CaSiO_4\ Ca(OH)_2$. It has a slight alkaline reaction and is completely decomposed by dilute hydrochloric acid. Optical and crystallographic data are given in detail.—P. N. **Chirvinsky**: Tyuyamunite from the Tyuya-Muyun radium mine in Fergana. A review is given of the literature on the copper, vanadium, and uranium ores at this locality. The mineral tyuyamunite, $CaO.2UO_3\ V_2O_5.mH_2O$, is related to carnotite, having calcium in place of potassium. The microscopical characters of the minute orthorhombic crystals are described.—L. J. **Spencer**. International agreement in mineralogical and crystallographical nomenclature. With a small amount of "give and take" in different countries much greater uniformity could be attained for mineral names. For international purposes the correct spelling of the printed word is of more importance than the correct pronunciation. There is no necessity to provide well-established mineral-names with the termination *ite*. The Millerian notation for crystal planes is the best for international use. The principal optical directions are conveniently given by α, β, γ, corresponding with the three principal indices of refraction.

EDINBURGH.

Royal Society, January 12.—E. Leonard **Gill**: The Permian fish, Dorypterus. The external covering of Dorypterus consisted only of a series of large scales protecting the belly, of a curious cord-like row of spindle scales and a few scales upon the tail. The bony structures of the few examples which have been preserved, show that it belonged to the coral-fish type, that its body was exceedingly compressed and roughly circular in outline, and that its jaws, differing from those of any other known fish from the earlier deposits, show it to have developed a highly specialised mode of feeding. Its flattened body, comparative lack of scales, and limited amount of muscular tissue, necessitated that exceptional support should be derived from the bony skeleton, and hence the median plane has become filled with a development of bony spines and fin-supports, such as is scarcely equalled in any other fish. In this and other respects it shows general and remarkable convergence of adaptation to modern flattened fishes of the "John Dory" type, while in the placing of its paired fins its aspect is also modern. The investigation demands the formation of a new family for "Dorypterus," and a readjustment of its recognised place in the scale of fish evolution.—E. A. **Baker**. The law of blackening of the photographic plate at low densities. This investigation was undertaken at the Royal Observatory, Edinburgh, in order to supply the necessary physical data for a photometric study of stellar spectra. Such a study leads to the characteristic curve of radiative intensity of each star, and the determination of its temperature. But a prerequisite is the conversion from density on the photographic plate to the intensity of the illumination, for any wave-length. The instrument for measuring density is a photometer, constructed by the author, on the principle devised by Koch, in which the obscured and unobscured beams pass to two photo-electric cells and their effects are balanced against one another. The production of standard deposits representing definite ratios of the incident light was effected by means of screens pierced by standard apertures, registering upon the same spot and exposed separately or together. The values for different wave-lengths were secured by suitable colour filters. These are at present confined to the violet and the red, the filters not being sufficiently selective in the green. The results are expressed in the form of the determination of certain coefficients, equivalent to, and superseding the current statements of the inertia of the plate, development constant, and the departure from reciprocity indicated by Schwarzschild's index.—E. L. **Ince**. The vibrations of a stretched membrane with a particular law of density. Membranes the density of which diminishes according to the square of the distance from a fixed point were considered. The boundary is either circular, elliptical, or rectangular. For particular values of the constants the problem is simpler than in the case of uniform density. These simple cases are considered, and the problem is then dealt with more generally by an appeal to the Sturmian theory of differential equations.

VIENNA.

Academy of Sciences, November 20.—J. **Kaess**: Fermat's great theorem and its solution.—A. **Rollett** and A. **Schmitt**: On β-amyrin from Manila elemi-resin (third contribution).—K. **Stosius** and E. **Philippi**: The course of the action of ammonia on cinnamic acid ethyl ester.—M. **Nicolic**: The influence of light on the germination of *Phacelia tanacetifolia*. The germinating power of the seeds is in part completely destroyed, in part hindered, by continued illumination. The retarding action of light increases with the strength of the illumination.—F. **Dormann**:

The epidermal glands and excretion of resin in *Alnus viridis*.

November 27.—The vice-president announced the death of Sir Archibald Geikie, honorary member of the Academy.—S **Meyer**: Communications of the Radium Institute, No. 171. Coefficients of atomic magnetism for the rare earths. New determinations with the purest material from C. Auer-Welsbach and for hafnium from G. Hevesy. Cassiopeium and hafnium are as diamagnetic as lanthanum and zirconium. Tetravalent præsodymium has nearly the same atomic magnetism as trivalent cerium, and tetravalent cerium nearly the same as trivalent lanthanum. The results are important for the co-ordination of electronic orbits in Bohr's atomic model.—J **Kaess**. Construction of the angle 1° with compasses and ruler.—G **Weissenberger**, F **Schuster**, and N **Mayer**. On the molecular compounds of the phenols, VI. The behaviour of naphthols, tetrahydronaphthol, and allied compounds.

December 4.—H **Pettersson**: Communication of the Radium Institute, No. 172. The field of force of the atomic nucleus and Coulomb's law. Experiments seem to show that α-particles shot at the nucleus of certain elements are not reflected but remain at the nucleus. This, as well as the results obtained by Bieler, can be explained by considering the electrostatic induction between α-particle and nucleus on the basis of Coulomb's law.—J **Kaess**. Division of a circle into 7 and into 9 parts by ruler and compasses.—L. **Holzer**. Estimation of the units in a cubic number-body (Zahlkörper).—F **Raas**. The crystal form of the orthoclases. The growth velocities of single crystal surfaces are given numerically as relative central distances.—R **Mueller**, E **Pinter**, and K **Prett**: The electrochemistry of non-aqueous solutions, Communication VI. Experiments on the electrolytic deposition of some metals from solutions in amyl alcohol, acetonitrile, aniline, and chinoline.—B **Guth**. On the chemistry of the higher fungi, Communication XVIII. Investigations on the muscarine problem.—J. **Zellner**. On the chemistry of heterotrophic phanerogams, Communication V. The parasite *Prosopanche Burmeisteri* contains special tannoids.—J. **Pia**: Remains of a land plant in the Noetsch coal strata in the eastern Gailtal Alps. A new fern, Gymnoneuropteris.

Official Publications Received.

United States Department of Agriculture. Department Bulletin No. 1235: Life History of the Codling Moth in the Yakima Valley of Washington. By E. J. Newcomer and W. D. Whitcomb. Pp. 77+8 plates. (Washington: Government Printing Office.) 15 cents.

Department of the Interior: Bureau of Education. Bulletin, 1924, No. 26: Statistics of State Universities and State Colleges for Year ending June 30, 1923. Prepared under the Supervision of Frank M. Phillips. Pp. 15. (Washington: Government Printing Office.) 5 cents.

Høst et fils.)

Methods and Problems of Medical Education. (Second Series.) Pp. 11+118. (New York: The Rockefeller Foundation.)

Diary of Societies.

SATURDAY, FEBRUARY 7

ROYAL SOCIETY OF MEDICINE (Otology Section), at 10.30 A.M.—L. Colledge: Demonstration of Kinematograph Pictures of Cases of Facial Paralysis treated by Nerve Anastomosis. G. J. Jenkins: Septicæmia as a Complication of Middle-ear Infection.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Dr. E. H. Fellowes: The Elizabethan Ayre.

GILBERT WHITE FELLOWSHIP (at 6 Queen Square, W.C.), at 3.—Dr. J. R. Leeson: The Evolution of Man.

INSTITUTE OF BRITISH FOUNDRYMEN (Lancashire Branch) (at Grand Hotel, Manchester), at 4.—V. C. Faulkner: A Psychological Examination of Foundry Life.

HULL ASSOCIATION OF ENGINEERS (at Hull Municipal Technical College), at 7.15.—J. Sim: Recent Developments in Marine Auxiliaries.

MONDAY, FEBRUARY 9.

ROYAL IRISH ACADEMY (at Dublin), at 4.15.

ROYAL SOCIETY OF EDINBURGH, at 4.30.—W. L. Calderwood: The Relation of Sea Growth to the Spawning Frequency in *Salmo salar*.—Prof. F. J. Cole: A Monograph on the General Morphology of the Myxinoid Fishes based on a study of Myxine. Pt. 6: The Blood Vascular and Lymphatic Systems.—Sir Thomas Muir: The Theory of Compound Determinants from 1900 to 1920.

VICTORIA INSTITUTE (at Central Buildings, Westminster), at 4.30.—Prof. A. T. Clay: The Amaru.

BIOCHEMICAL SOCIETY (in Biochemical Department, University College), at 5.—H. J. Channon: Cholesterol Synthesis in the Animal Body.—G. A. Harrison and H. J. Channon: Observations on the Composition of Subcutaneous Fat in Cases of Sclerema Neonatorum.—C. R. Harington, S. A. S. Tri-iodophenyl-pyrollidone-carboxylic Acid.—J. C. Drummond and K. H. Coward: (*a*) Further Observations on the Chemical Nature of the Vitamin Fraction of Cod Liver Oil, (*b*) Ultra-violet Radiation and Growth.—S. Tsubura: Comparison of the Reducing Properties of Plain and Striated Muscle.—Dr. P. Hass and T. G. Hill: An Oxygen Absorbing Mechanism in *Mercurialis perennis* and Accompanying Colour Changes.—A. Wormall: The Tyrosinase-tyrosine Reaction: the Theory of Deamination.—F. C. Happold and H. S. Raper: The Supposed Deaminising Action of Tyrosinase on Amino Acids.—C. Rimington and H. D. Kay: The Phosphorus of Caseinogen (Preliminary Communication).

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. V. E. Negus: Some Disorders of the Larynx.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—Capt. P. P. Eckersley and others: Discussion on Broadcasting.

INSTITUTION OF MECHANICAL ENGINEERS (Graduates Section), at 7.—K. Rowell: Recent Developments in Solid Injection Oil Engines.

INSTITUTE OF METALS (Scottish Local Section) (at 39 Elmbank Crescent, Glasgow), at 7.30.—J. A. Gardner: Methods of Keeping Foundry Records.

ROYAL SOCIETY OF MEDICINE (Epidemiology and State Medicine, Comparative Medicine, Disease in Children Sections), at 8.—Dr. Robertson, Dr. Niven, and others: Special Discussion on The Control of Tuberculosis and the Milk Supply.

SURVEYORS' INSTITUTION, at 8.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—J. M. de Navarro: Ancient Trade Routes in Europe.

MEDICAL SOCIETY OF LONDON (at 11 Chandos Street, W.), at 8.30.—Sir Thomas Horder, Bart., and others: Discussion on the Treatment of Lymphadenoma.

TUESDAY, FEBRUARY 10.

ROYAL SOCIETY OF MEDICINE (Therapeutics and Pharmacology Section) (at National Institute for Medical Research), at 4 30.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15 —Prof J Barcroft: The Colour of the Animal Creation (I) The Colour of Man.

ROYAL SANITARY INSTITUTE, at 6 —Maj.-Gen Sir Wilfred Beveridge, Dr W M Willoughby, and others Discussion on Food and Health

INSTITUTE OF MARINE ENGINEERS, at 6 30 — Presidential Address

INSTITUTION OF ELECTRICAL ENGINEERS (East Midland Sub-Centre) (at the College, Loughborough), at 6 45 —S Ferguson: A General Survey of the High Tension Switchgear Field

INSTITUTION OF AUTOMOBILE ENGINEERS (at Royal Society of Arts), at 7 —F. G Woollard British Methods of Continuous Production.

INSTITUTION OF ELECTRICAL ENGINEERS (North Midland Centre) (at Hotel Metropole, Leeds), at 7.—Informal Discussion on Domestic Electrical Apparatus

ROYAL PHOTOGRAPHIC SOCIETY (Scientific and Technical Group), at 7 — Conference on the Standardisation of Plate Testing Methods: —Section IV The Measurement of Photographic Densities (*a*) Survey of the Present Position, (*b*) Standardisation of Photographic Densities, (*c*) Methods of Measurement Opening Paper by Dr C E Toy —Section V The Interpretation of Results (*a*) Plate Speeds The Hurter and Driffield and other Systems, (*b*) Inadequacy of these Systems Rôle played by the under, correct and over exposure portions of the plate curve Opening Paper by T Thorne Baker and O Bloch

INSTITUTION OF AUTOMOBILE ENGINEERS (Coventry Graduates Meeting) (at Broadgate Café, Coventry), at 7 15 —G H Day: Aluminium its Alloys and their Use in the Automobile Industry

INSTITUTION OF ELECTRICAL ENGINEERS (Scottish Section) (at 207 Bath Street Glasgow), at 7 30 —H W Taylor Three wire Direct-current Distribution Networks Some Comparisons in Cost and Operation

INSTITUTION OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND (at 39 Elmbank Crescent, Glasgow), at 7 30

QUEKETT MICROSCOPICAL CLUB, at 7 30 —D J Scourfield Asymmetry among Microscopic Organisms (Presidential Address)

INSTITUTION OF MECHANICAL ENGINEERS (Swansea Meeting)

WEDNESDAY, FEBRUARY 11

INSTITUTION OF HEATING AND VENTILATING ENGINEERS (at Old Colony Club, Aldwych House, W C) (Annual General Meeting), at 2 30: A H Barker Unsettled Questions in Heating and Ventilation

ROYAL SOCIETY OF ARTS, at 4 30 —Sir J Fortescue Flannery, Bart The Diesel Engine in Navigation

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 —Prof R L Knaggs Osteitis Deformans, and its relation to Osteitis Fibrosa and Osteomalacia

BRITISH SOCIETY OF MASTER GLASS-PAINTERS (at 6 Queen Square, W C), at 6 —W E Tower The 14th Century Glass of Tewkesbury and its Recent Repair

SOCIETY OF CHEMICAL INDUSTRY (Glasgow Section, jointly with the Glasgow University Alchemists' Club and Institute of Chemistry) (at Glasgow University), at 7 —R B Pilcher Alchemists and Chemists in Art and Literature

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Graduate Section) (at Bolbec Hall, Newcastle on Tyne), at 7 —F H. Todd The Capital Ship as affected by the Washington Conference

INSTITUTION OF AUTOMOBILE ENGINEERS (Wolverhampton Centre) (at Wolverhampton), at 7 30 F G Woollard British Methods of Continuous Production

INSTITUTION OF CHEMICAL ENGINEERS (jointly with the Chemical Engineering Group of the Society of Chemical Industry) (at Institution of Mechanical Engineers), at 7 30 —O Brunler Internal Combustion Boilers — D. Brownlie Steam Generation under Critical Conditions

EUGENICS EDUCATION SOCIETY (at Royal Society), at 8 30 —Dr B Malinowski Mate Selection in Primitive Society

THURSDAY, FEBRUARY 12.

ROYAL SOCIETY, at 4 30 —H Muir Evans A Contribution to the Anatomy and Physiology of the Air Bladder and Weberian Ossicles in Cyprinidæ —J S Huxley Studies on Amphibian Metamorphosis, II —*To be read in title only* —Prof A Dendy An Orthogenetic Series of Growth Forms in certain Tetraxonid Sponge Spicules — Dr C E Walker. The Meiotic Phase in Triton (*Molge vulgaris*) —W E Atkins *Clausilia bidentata* (Strom) and *Cl. cravenensis* (Taylor): A Statistical Enquiry into the Relationship of two Similar Species

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15 —Sir William Bragg The Properties and Structure of Quartz (III)

ROYAL AERONAUTICAL SOCIETY, at 5 30 —Col F Searle The Maintenance of Commercial Aircraft

ROYAL SOCIETY OF MEDICINE (*Tropical Diseases and Parasitology Sections*), at 5.30 Dr A F MacCallan: Ophthalmology in Egypt —Capt W. H Dye Schistosomiasis and Splenomegaly in Nyasaland

INSTITUTE OF MARINE ENGINEERS, at 6 30

SOCIETY OF CHEMICAL INDUSTRY (Birmingham and Midland Section) (at Birmingham University), at 7 15.—Dr J Newton Friend. Iron in Antiquity

INSTITUTION OF ELECTRICAL ENGINEERS (Dundee Sub-Centre) (at University College, Dundee), at 7 30 — Prof A R Fulton: The Utilisation of Tides for the Production of Power

INSTITUTION OF ELECTRICAL ENGINEERS (Irish Centre) (at Trinity College, Dublin), at 7 45 — J H Shaw: The Services of the Electrical Engineer in the Post Office

OPTICAL SOCIETY (at Imperial College of Science and Technology), at 8.—Annual General Meeting —Dr A. Barr: Presidential Address

OIL AND COLOUR CHEMISTS ASSOCIATION (at 8 St Martin's Place, W C.), at 8 —A A. Drummon Synthetic Resins.—R G. Browning: The Painting of Ships

SOCIETY OF DYERS AND COLOURISTS (Bradford Junior Branch) (at Bradford).—W. White: Wool Printing.

FRIDAY, FEBRUARY 13.

DIESEL ENGINE USERS' ASSOCIATION (at Engineers' Club, Coventry Street), at 3 30 —P. A. Holliday: Submarine Engines and High-speed Heavy-oil Engine Electric Generating Sets.

ROYAL DUBLIN SOCIETY, at 4 30.

ROYAL ASTRONOMICAL SOCIETY, at 5 —Annual General Meeting —Prof. Eddington, Dr Jackson, Mrs. Maunder, and Prof. Milne: The Progress of Astronomy —Prof Fowler and Prof. Newall The Meeting at Cambridge of the International Astronomical Union —Dr. Dreyer: Tycho Brahe's Observations, Methods, and Results.

PHYSICAL SOCIETY OF LONDON (at Imperial College of Science and Technology), at 5 —Annual General Meeting —F E Smith: A System of Electrical Measurements (Presidential Address).

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 —Prof. S Cade: Regional Anæsthesia

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7.—Discussion on Gear Production Machinery.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—M Adams. Concerning Children and Photography

INSTITUTE OF METALS (Swansea Local Section) (at Swansea University College), at 7 15 —Dr H Moore Season Cracking and its Prevention.

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (at Technical College, Swansea), at 7 30 —C A Seyler Microscopic Structure of Coals

JUNIOR INSTITUTION OF ENGINEERS, at 7 30 —L. Pendred Milestones in the Development of the Prime mover Locomotive

INSTITUTE OF METALS (Sheffield Local Section, jointly with the Sheffield *Metallurgical Association and other Societies*) (*at* 198 West Street, Sheffield), at 7 30.—Dr C. H Lander Fuel and its Efficient Utilisation.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Literary and Philosophical Society, Newcastle on-Tyne), at 7 30 — J W Hobson The Internal-combustion Locomotive.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9 —Dr B Malinowski: The Forces of Law and Order in a Primitive Community

SOCIETY OF DYERS AND COLOURISTS (Scottish Section) —I. E Weber. Hydrogen Peroxide and Bleaching

SOCIETY OF DYERS AND COLOURISTS (Manchester Junior Branch) (at Manchester).—K H Saunders A Paper

INSTITUTION OF MECHANICAL ENGINEERS (Leeds Meeting)

SATURDAY, FEBRUARY 14

ROYAL INSTITUTION, at 3 — W Rothenstein The Artist's Relation to Social and Religious Life (I)

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 4 —Sir D'Arcy Power. Hunterian Oration.

INSTITUTE OF METALS (London Local Section) (at Institute of Marine Engineers), at 7.30 —V C Faulkner Some Notes on Refractory Materials

PUBLIC LECTURES.

SATURDAY, FEBRUARY 7

HORNIMAN MUSEUM (Forest Hill), at 3 30 —R P G. Denman. The Development of Modern Radio Communication.

MONDAY, FEBRUARY 9

LONDON SCHOOL OF ECONOMICS AND POLITICAL SCIENCE, at 5 —Dr E B. Behrens: International Labour Organisation

BIRKBECK COLLEGE, at 5 30 — Dr G. G. Coulton Chapters in Medieval Education (II) Song and Grammar Schools

KING'S COLLEGE, at 5 30 —S Smith. The Nature and Influence of Babylonian Literature

UNIVERSITY COLLEGE, at 5 30 —Lt.-Commdr. E Sutton: Buddhism (Succeeding Lecture on February 16)

TUESDAY, FEBRUARY 10.

KING'S COLLEGE, at 5 30 — Dr E. Bevan The Hebrew and Greek Idea of God with special reference to Philo of Alexandria.

UNIVERSITY COLLEGE, at 5.30 —Dr C F Sonntag Man's Place in Nature (I). (Succeeding Lecture on February 24)

SIR JOHN CASS TECHNICAL INSTITUTE, at 8 — S. O Neville The Fermentation Industries

UNIVERSITY OF LEEDS, at 8 —Dr. W. H. Pearsall: Age and Development of Moorland Peat.

WEDNESDAY, FEBRUARY 11

ST. BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE (Physiology Department) (6 Giltspur Street, E C.), at 5 —Dr J M Duncan Scott The Medullary Centres (I) (Succeeding Lectures on February 18, 25, March 4.)

LONDON SCHOOL OF ECONOMICS AND POLITICAL SCIENCE, at 5.—J. Adams The Principles of Design as applied to Pots and Pans

KING'S COLLEGE, at 5 30 —Sir Thomas Arnold: Arab Travellers and Merchants, A.D. 1000-1500

THURSDAY, FEBRUARY 12.

KING'S COLLEGE, at 5.30.—Prof. W. E. Soothill: China's Contribution to Western Civilisation

CENTRAL LIBRARY, 598 Fulham Road, at 8.—W P. Westell: Regional Survey.

FRIDAY, FEBRUARY 13.

KING'S COLLEGE, at 5.30 —Prof E Prestage: Vasco da Gama and the Discovery of the Sea Route to India

SATURDAY, FEBRUARY 14.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—B. Lovett: Natural History in Folk-lore.

SATURDAY, FEBRUARY 14, 1925.

Preservatives in Foods.

THE difficulty of drawing inferences of value in practical life from experimental work on animals or from observation on man could not be better illustrated than in the vexed question as to the legitimacy of allowing preservatives, especially boron preparations, in human foods. It is known that these preparations, when given steadily and persistently to animals, provoke renal inflammation ; it is commonly agreed, notwithstanding occasional medical testimony to the contrary, that they may be irritant to the human alimentary tract, and that they should be barred for young children, for invalids, and for sick persons It is also agreed that the elimination of a single dose of boric acid is slow, occupying five or six days, and that, therefore, most of us who live in towns are probably never free from boric acid in our systems from youth to old age It is, furthermore, common knowledge that boric acid or its salts are used largely in cream, butter, liquid eggs, margarine, potted meats, and are dusted over imported bacon and ham ; and that a person indulging in a varied diet may not impossibly, day by day, take an amount of boric acid which, even by the defendants of boron preservatives in food, would be regarded as inadvisable, if not actually injurious.

These and like considerations were before the Departmental Committee of 1900 and the more recent committee, the interim and final reports of which were summarised in the issues of NATURE for September 20 and December 13, 1924

The Committees also had before them the important consideration that the use of boron preparations is not unlikely to foster the continuance of less cleanly processes of food preparation and to conceal incipient and possibly dangerous stages of decomposition of food In this connexion, it is noteworthy that the prohibition of any preservative in milk has proved most successful, and has doubtless led to increased cleanliness in its production, transport, and storage. It has also been associated with increased use of pasteurisation, which may in some measure permit the continuance of relatively unsatisfactory production of milk , but, even so, pasteurised milk or cream represents a hygienic advance upon boricised milk or cream It is not surprising, therefore, that the recent Committee recommends that the use of boron preparations as food preservatives should be prohibited ; and the Minister of Health has indicated his intention to make draft regulations for this purpose. (For the sake of brevity, boron preservations alone are considered in this article)

Already there are indications that the proposed regulations will not be universally approved. Sir William Pope, professor of chemistry in the University

of Cambridge, has advanced in the *Times* weighty points for consideration. He regards the evidence of injury by boron preservatives as not convincing, and stresses the complexity of factors involved in human experimentation with such preparations, owing to the diverse factors concerned in the balance of health and disorder. Similarly, Dr. R Hutchinson writes stating that if injury from such preparations occurs, "it has entirely escaped the notice of medical men." Also, Prof F. W Tunnicliffe considers that in deciding against the use of boric preservatives "*a priori* argument has been drained to its dregs," and inadequate attention has been paid—as Sir William Pope had already suggested—to the danger of dearer and scarcer food, as the result of the prohibition of preservatives for perishable foods needing to be transported long distances At the least it appears to be suggested, let us postpone the prohibition of boric preservatives until the mass processes of production and transportation of perishable food have become perfected. Great waste of food is avoided by mass production Mass production is indispensable under modern conditions of life, and the means of transport within Great Britain do not permit, it is urged, even if those from other countries permit, of cold storage and transportation, to an extent which will avoid much waste of valuable food, if preservatives are forbidden.

As indicating the way in which politics may influence hygienic control, it is suggested that the prohibition of boric preservatives in Germany is, in part at least, enforced in order to keep out Canadian and American bacon and ham. The same effect might follow from a similar prohibition in Great Britain; and so we have illustrated the struggle and conflict of motives and aims which almost necessarily arise when any reform which is theoretically desirable is proposed. Motives of preferential trading may arise, the plea is entered that the proposed action will involve the wasting of much perishable food, and it is contended—as may easily be done—that the evidence of injury from the preservatives proposed to be prohibited is dubious and may even be non-existent.

These are reasons for proceeding cautiously, and there need be no extravagant fear that the Ministry of Health will proceed otherwise. But that the use of chemical preservatives is undesirable is, we think, indisputable, that their restriction and their extended restriction should be enforced, follows as a desirable reform, and in our view this restriction is not likely to be followed by increased scarcity of food, for we have every confidence in the ability of those concerned to improve their methods of manufacture and of transport, so as to obviate the need of any preservative except cold.

In deciding a complex practical problem like this, we are bound to consider the weaker members of the community, for whom doses of boric preservatives not producing recognisable symptoms in the majority, are likely to be serious, and this consideration alone suffices, we think, to justify extension of the present regulations against food preservatives in the direction recommended by the recent Departmental Committee. It has been urged that in this connexion Solon's advice to the Athenians should be followed: Have the best laws that can be kept, not the best laws that can be made. But past experience has shown that gradually increasing stringency in regulating food preservatives can be enforced, and that it is associated with better processes of preparation and transportation of food, and the next steps in this direction may be expected to have similar results.

Philosophical Biology.

(1) *The Study of Living Things: Prolegomena to a Functional Biology.* By Dr. E S. Russell. Pp. xx + 139. (London: Methuen and Co., Ltd., 1924.) 5*s.* net.

(2) *The Passing of the Phantoms: a Study of Evolutionary Psychology and Morals* By Prof. C. J. Patten. Pp. 95 + 4 plates. (London: Kegan Paul and Co., Ltd; New York: E. P. Dutton and Co., 1924.) 2*s.* 6*d.* net

(3) *Tantalus: or the Future of Man.* By Dr. F. C S. Schiller. Pp. 72. (London: Kegan Paul and Co., Ltd., 1924.) 2*s.* 6*d.* net.

As the reading public gradually accepts the doctrine of evolution and its corollary, the unity of life, a demand arises for books which deal, on one hand, with the application of biological methods and ideas to human life, and on the other, with an analysis of those ideas. With the narrowing of the gulf between man and the other animals, we find a quite legitimate tendency to interpret the mind of animals in terms of the human mind, and conversely. But such a procedure demands enormous caution, and one can scarcely hope to find the necessary critical attitude in books which are written to defend a point of view rather than to examine all sides of a problem. Yet they may justify themselves if they are sufficiently stimulating or attractive.

(1) Dr. Russell's book deals with the various methods by which biological problems may be attacked. After a passing reference to the purely morphological point of view, he briefly examines and rejects the materialistic conception of life, and points out its failure to explain the unity of the organism. Vitalism, that is, the theory that an organism consists of inert matter plus a soul or entelechy, is shown to have its own difficulties without solving those of materialism. So far Dr. Russell is in agreement with J. S. Haldane, whom

he quotes at length. But he regards Haldane's position as essentially a half-way house, also tenanted by J. B. Watson, to his own psychological outlook. "I know myself," he says, "as a psycho-physical unit or individuality, not as an immaterial entity acting upon an external material object, my body." It is from this point of view that he considers the behaviour of other organisms as exemplified not only by movement and secretion, but also by such activities as growth. The latter half of his book is taken up with the attempt to apply this view in detail. For example, it is suggested that the growth-regulating secretion of the thyroid gland "acts not directly by virtue of its specific chemical constitution, but indirectly by virtue of its meaning or significance, being perceived or sensed in an elementary way by the organs and responded to in the functional or psychobiological sense."

Apart from his complete neglect of such difficulties for a monadistic view as are presented by fission or conjugation, for example, we are inclined to regret that Dr. Russell does not push this point of view to its logical conclusion. From a strictly psychological point of view he has no business to talk about internal secretions, and adrenaline, for example, is not an aromatic amine from his point of view, but simply an element in certain emotional states. As it is, we feel that he tends to use physics and chemistry so long as they suit him, and adopts a psychological point of view when the complexity of the physico-chemical situation becomes intolerable. But few biologists achieve consistency in their hypotheses, and we can recommend Dr Russell's book to all who are interested in the philosophical side of biology.

So far man has only learned to think on two lines, one which enables us to deal with our fellow-men and the higher animals, the other with inanimate objects; but it does not follow that these are the only possible types of thought. Perhaps some intermediate outlook, which preserves the unity attributed to the human individual though without his memory or foresight, may prove valuable in dealing with lowlier organisms or with our own unconscious behaviour.

(2) Prof. Patten's book, after a thumb-nail sketch of evolution, plunges into animal psychology; and human attributes, such as admiration, imagination, and superstition, are assigned to birds and mammals. The bearing of animal on human psychology is discussed, with special reference to the origin of human superstitions, which include all beliefs in supernatural beings. The book makes no attempt to be either scientific or exhaustive, but it is so charmingly written that we believe it will find many readers. It is clear that the author is a real lover of animals, and if his love leads him into a perhaps unduly confident belief that they are on the whole virtuous and happy, it inspires a number of delightful anecdotes of animal behaviour. His religion, a sunny rather than philosophical pantheism, springs directly from his love of Nature. There is little that is novel in the book, but the author's point of view is worth restating from time to time. As a means of bringing home the reality of evolution to the average child of sixteen or so, we feel that it might be of real value in school libraries.

(3) "Tantalus," who here represents humanity as a whole, is a philosopher's reaction to biology The reaction is sometimes rather naive, as when he pauses to wonder that from the biological point of view man has not evolved in the last thirty thousand years. Critics of their fellow-creatures, and particularly of the present Government, would do well to remember Lingula, which has scarcely changed in the three million or so centuries that have elapsed since Ordovician times Dr. Schiller very rightly stresses the fact that in our society those social classes which we admire most are reproducing themselves most slowly, but some of the reasons given for this fact are, to say the least, unconvincing For example, the author alleges that the advance of medicine has enormously diminished selective mortality and improved the chances of weaklings to survive and leave descendants The contrary case could be argued, for in the last two centuries epidemic diseases such as smallpox have almost disappeared, and more chronic complaints such as tuberculosis, which kill far less indiscriminately, have remained with us The question whether the differential birth-rate may not be due to certain economic features of our civilisation rather than to its philanthropy and hygiene is scarcely considered.

With regard to the traditions which constitute man's non-biological inheritance, Dr. Schiller is equally gloomy. Perhaps it is a too intimate acquaintance with compulsory chapel and university examinations which prompts him to ask, "How many religions have perished from ritual sclerosis, how many sciences have not been degraded into pseudo-sciences or games?" He suggests two ways out of the impasse, one being the practice of Christian ethics, the other of eugenics He believes that history has shown that humanity as at present biologically constituted will not accept the former. He has more hope of the latter, provided we realise that our whole procedure is essentially experimental. He has also some confidence in the future of applied psychology. The scientific reader who is interested in the reaction of biological ideas on the mind of an intelligent outsider, or wishes to see the case for eugenics briefly stated without the display of too much class or racial prejudice, would do well to buy this little essay. J. B. S. H.

MEN of science, in the first instance dubbed "Improvers," have been continuously at work for at least a century and a half investigating such problems as those involved in animal- and plant-husbandry, manuring, and the mechanics of agriculture. Systematic study of the other, or economic, side of the industry has been undertaken only within the last decade Research work under this head may imply the compilation of elaborate cost-accounts, comparison of various methods of farming, investigation into the pros and cons of large or small-holdings or the distribution of various forms of land-tenure, inquiry into the profits accruing to each class of person engaged in the industry, study of marketing systems, and so on. Into each of these fields individual workers have gone before, but that all-important factor, continuity of effort, has, until recently, been lacking. It is, for example, possible to recover the most elaborate records of the working of particular manors more than six hundred years ago ; in the seventeenth century Henry Best minutely investigated what we should now describe as the "economy" of North-country farming ; a hundred years ago, full statements of farm accounts kept in Norfolk and other arable counties were published

Generally, the efforts of those responsible for these pioneer investigations were ridiculed ; at best they were made the subject of acute controversy. For example, in Scotland, the publication in 1823 of an article "showing the expense and value of the produce of a Lothian farm during the late war" was thus welcomed by an anonymous farmer : "Try Mr. Scott's statement by what standard you may, and inform me wherein consists its merits. If it be considered a production of imagination, or of reflection, it is inferior to a nursery tale , as a work of instruction, or of utility, it is fallacious and ill-judged , as a statement of Lothian husbandry it is little short of a libel." Again, an eighteenth-century advocate of small farms thus delivered himself to a pamphleteer on the opposite side · "The fiend who wrote this was in all probability never beyond the stench of the infernal abode wherein he dwells !"

If controversies are still engendered on the latter subject, and apathetic reception upon occasion rewards the efforts of Mr Scott's successors, there is no doubt that the vast majority of agriculturists appreciate that there exists nowadays a new, and possibly valuable, means of approaching rural problems. In Great Britain, since the War, successive Governments have granted increasing sums towards the extension and maintenance of services charged with investigational and advisory duties. Nor is interest confined to this country, for, judging from reports emanating from Japan, the United States, Switzerland, and Denmark, it may be confidently stated that the movement towards a closer study, and therefore a better understanding, of farming conditions and rural economics is widespread. A natural corollary is the appearance of numerous publications, either dealing with the history and general principles of the subject, or confined to particular sections. In both classes the United States is well represented

(1) The first book on our list comprises an elaborate analysis of the utilisation of American soil. Its authors have produced a work which is bound to be of considerable value to American students, and one that is very suggestive to those European readers who are interested in the problems raised during the transition of a vast territory from a natural condition to a state aptly illustrated by the frontispiece, entitled "Airplane view of Manhattan Island, New York City." The distribution of the various categories of soil is well described, and successive chapters deal with its utilisation, for his varying requirements, by man, his access to forest and mineral products, and the provision of credit ; they also touch on what are to us such familiar and vexed questions as the taxation of "increments in land values." The volume is well produced and contains excellent diagrams and illustrations, but it contains scarcely any reference to conditions existing elsewhere.

(2) Dr. Gray's book is of more general interest to European readers. The author is an official of the United States Department of Agriculture, and he has produced a book which covers a wide field, ranging

from the enunciation of general economic theories down to advice on the marketing of fruit. He does not disdain reference to conditions existing in other countries, and his views on numerous rural problems will be read with respect by students therein. His twenty-six chapters all conclude with "Questions on the text," which do not detract from their value, but tend to emphasise the American origin of the work itself. The diagrams are excellent; particular praise must be given to the maps, produced by the author's own Department, showing the distribution of crops and of different-sized farms, a form of activity in which Great Britain has hitherto lagged behind the United States; fortunately, however, within a short time matters will have been rectified in this respect. Dr. Gray's work is admirably produced, and its moderate bulk is disproportionate to the number of its pages.

In (3) is found a work from the pen of a professor of political economy, which, to British ideas, is more orthodox in its treatment of the subject. The general history of agriculture is not neglected, for reference is made to village communities and the manorial system, and the names of certain English writers of long ago are mentioned. The author exercises considerable restraint when dealing with such contentious questions as co-operation and land-tenure, and has always at hand appeals to economic laws to enforce his arguments. He has produced a small, but scholarly, work which will not only be read with interest by British economists, but will also be retained on their bookshelves. Diagrams similar to those above referred to are again prominent.

(4) Mr. Orwin is undoubtedly the recognised authority on farm accounts in Great Britain, and it is largely through his persistent efforts during recent years that the great advantages to be obtained from the accurate keeping of "costings" has gained wider recognition amongst the farming community. In the latest edition of his book will be found clearly mapped out the procedure to be followed in farm costing. The author has enumerated the various principles involved in a straightforward way which should make the volume of the greatest use to farmers and students who have had no very great experience in book-keeping. The underlying principle to be grasped is that the balances of the apparently unproductive accounts (for example, labour, rent, foods, and manures) are charged against the productive accounts in the proportions in which the latter have benefited from them. This involves the keeping of records of labour, both manual and horse, and of rations fed to stock. Mr. Orwin gives examples of appropriate labour and ration sheets, and explains the method of their analysis; complete and up-to-date cost accounts of a Gloucestershire farm add to the value of the latest edition of what is admittedly a standard work in its subject.

Mr. Holmes in (5) has somewhat missed the aim of his endeavour to maintain simplicity as the primary object in preparing this volume. Those farmers for whom his book is intended as a guide will be inclined to give up the task of trying to master costing principles when they read that not only must a record be kept of the number of days grazed by each class of stock, and these eventually converted into "sheep-equivalents," but also that the manurial residues of foods fed on pastures must be calculated. It is not to be denied that such records can be kept with advantage on certain types of holdings, but on small farms, and where live stock is of diverse types and ages, it is questionable whether the degree of accuracy with which such information could be compiled would warrant the laborious calculations involved. Mr. Holmes advocates the "Standard" method of valuing cows and breeding stock. In this he is undoubtedly right, as in times of fluctuating prices, paper profits and losses are thus eliminated. The volume contains a full set of accounts for the year 1920–21 on a dairy farm of some two hundred acres.

As a text-book designed for school study in the United States, (6) can be recommended on account of the large number of exercises and "Topics for discussion" appended to each chapter. The first part deals with methods of making an inventory and financial statement, the second is confined to financial accounts, while the third deals with cost accounts and methods of recording data. As a treatise for British readers it is of interest in presenting arguments in favour of the adoption of general principles other than those commonly recognised in this country. Some of those advocated are open to criticism. For example, the authors recommend that interest on the average investment of capital in each branch of the farm should be charged against its cost, and also that a charge should be made against cost for the value of the farmer's own labour. Again, in regard to home-produced foods fed on the farm, they state that "an intermediary product which may readily be marketed should be charged at its farm value and not at its cost of production. Other intermediary products should be charged at their cost of production." The accepted practice in Great Britain, that of charging all intermediary products at cost price, appears to be much the sounder of the two methods. The volume contains cost accounts typical of conditions in Kansas and Iowa. American currency, however, and such expressions as "chores," "shelling," and "snapping corn" render them of doubtful utility outside the continent of North America.

J. A. VENN.

The Chemistry of Flour Milling.

Modern Cereal Chemistry. By D. W. Kent-Jones. Pp. ix + 324 (Liverpool: The Northern Publishing Co., Ltd., 1924.) n p

THE chemistry of wheat flour, and the elucidation of the factors influencing the "strength" or baking quality of flours from different wheats, present problems as complicated and difficult as any to be found in food chemistry. Recent research has thrown much light on some of these problems, and the author, who is well known as an authority on flour chemistry, is to be congratulated on having given a connected and critical account of the important work done on this subject during the last few years.

The English miller draws his wheat from almost every wheat-producing country in the world. Many of these wheats differ enormously in their strength or ability to produce a good loaf, that is to say, a large well-risen loaf possessing a certain silky and finely vesiculated texture. The author, in his chapter on the colloidal chemistry of flour, discusses the relative importance of various factors in the production of strength. The actual amount of gluten present and its physical character, the degree of colloidal dispersion of gliadin and glutenin, the hydrogen ion concentration of flour and the extent to which it is "buffered," the enzymic activity of the flour and the relative amount of yeast food present, are all more or less concerned in determining strength or weakness in a flour. The author is clearly on good terms with the most recent work on the colloidal chemistry of flour, and has given in this chapter an able review of present-day knowledge in this field.

It is when the author comes to the chapter on bleaching and flour improvers, on p. 165, that he treads heavily on dangerous ground. He adopts wholeheartedly the attitude that the artificial bleaching and improving of flour by nitrogen peroxide, chlorine, nitrogen chloride, peroxides, persulphates, acid phosphates, etc., is completely justifiable and beneficial both to the trade and to the consumer. In fact, he is at such pains to emphasise the entirely harmless character of these additions that the suspicions of the reader may well be aroused, and he may be led to inquire more closely whether the introduction of one pound of pure chlorine gas into a ton of flour is, in fact, entirely without effect on the consumer's health, whether there may not be some subtle action on the flour, affecting, ever so slightly, those vital principles which food manufacturers are never tired of claiming for their products, and whether the oft-repeated argument that no one has ever been able to prove injury to health from such additions is good enough where the most important foodstuff of all is concerned. To attempt an answer to these questions would, however, be outside the province of a reviewer.

The concluding chapters dealing with conditioning, moisture in wheat and flour, and analysis of flour are excellent. The book may be warmly recommended to all interested in the chemistry of flour, on the understanding that the Report of the Departmental Committee on the Use of Preservatives and Colouring Matters in Food be glued to p. 165. G. W. M.-W.

New Measurements of Atomic Masses.

Isotopes. By Dr. F. W. Aston. Second edition. Pp. xi + 182 + 5 plates. (London: E. Arnold and Co., 1924.) 10*s.* 6*d.* net.

IT is seldom that a natural philosopher has made a subject so peculiarly his own as Dr. Aston has done with the experimental investigation of isotopes. At the present time, about fifty non-radioactive elements have been examined for isotopes, and all except half-a-dozen or so are among Dr. Aston's trophies. It is not, apparently, so much that other workers have stood aside as that the technique is not quite so simple as a casual description of the experimental method might suggest to the inexperienced. About two years ago, Dr. Aston published a general account of his work since the War under the title "Isotopes," and, as was to be expected, a second edition was soon demanded, which has now made its appearance.

As reference to the table of isotopes on p. 107 will immediately show, in the interval of two and a half years, more than twenty new elements have been investigated for isotopes by the author, so that at the time of writing, all the elements from atomic number 1 to atomic number 39 have been worked through, and many in the range 39 to 80. A beginning has been made with the elements of the rare earth group. The additions are mainly due to the development of the method of accelerated anode rays by the author. A salt of the metallic element to be investigated is made into a paste with graphite, and this paste, packed into a small tube, is used as the anode, and bombarded with cathode rays. The instability of the discharge consequent on the release of gas from the anode is avoided by a skilful device consisting of a subsidiary cathode and a kenotron valve. It is indicative of the troublesome nature of the work that even Dr. Aston himself records that when the apparatus was working sweetly, he analysed six elements successfully in as many working days, but that after it had been dismantled and set up again so as to be, apparently, exactly the same as before, he was unable to obtain any results of value for some weeks. When conditions are favourable the method gives excellent results.

The accuracy which Dr Aston now obtains in his measurements is emphasised by the fact that he is able to direct attention to a departure from the whole number rule shown by certain isotopes, notably those of tin This departure of the atomic mass from a whole number (oxygen, of course, being taken as 16) amounts to only two or three parts in a thousand, yet seems to be definitely established. It does not appear possible at present to draw any very precise conclusion from this observation. To avoid disturbing our ideas the effect may be attributed, in a general way, to some "close packing" of the same kind as prevents the masses of the general isotopes being whole numbers in terms of hydrogen as unity, but so little is known of the structure of complex nuclei that this is, in effect, simply a shelving of the matter until further measurements, of even higher accuracy, shall become possible The few cases of departure do not appear as such in the tables of isotopes, since a new term, "mass number," has been introduced in place of the old "mass of isotope" This is defined either as the number of protons in the nucleus or as the nearest whole number to the mass expressed in terms of oxygen as 16: both definitions amount to the same thing Since the departure is a minor matter, at any rate in the present state of our knowledge, this term is a timely one which serves, as good terms should do, to avoid inaccuracy on one hand and circumlocution on the other

The book contains many references to relevant results of other researches which have been carried out in the last two or three years, such as the work of Rutherford and Chadwick on nuclear disintegration, and the investigations of Ellis on nuclear γ-rays A rather fuller account of Fajans' speculations on relative stability of nuclei might have been welcome, since they are both more intelligible and more fruitful than most of the conjectures on this subject. The detection of an isotope effect in band spectra is also discussed, but, it may be said, it is by no means certain that the boron nitride bands of Jevons, on which there has recently been discussion in the correspondence columns of NATURE, are really monoxide bands, as Mulliken wants them to be, theoretically desirable as it may be for them to be so.

The paper on which the second edition is printed is a great improvement on that of the first, and it is pleasant to be able to acknowledge, in these dear days, that the book is very reasonably priced. In place of a final word of commendation, which is superfluous in this case, may be ventured the anticipation that in another year or two Dr. Aston will bring out a new edition recording the remaining thirty or so non-radioactive elements as satisfactorily sorted out into their isotopes. It seems very probable. E. N. DA C. A.

Our Bookshelf.

The Year-Book of the Scientific and Learned Societies of Great Britain and Ireland: a Record of the Work done in Science, Literature and Art during the Session 1923–1924 by numerous Societies and Government Institutions Compiled from official sources Forty-first annual issue Pp. vii+405. (London: C Griffin and Co., Ltd., 1924) 15s net.

THE issue of this Year-Book for 1922–23 did not appear until the summer of 1924 this was somewhat late for a reference book dated for 1923. The publishers deserve our gratitude, therefore, for the promptness with which they have produced the volume for 1924 This forty-first issue has already started on a career of usefulness in our hands, which will continue until, and even after, the volume for 1925, which we hope to see in due course, has been published

Compared with last year's Year-Book, that for 1924 has been increased by sixteen pages, and we understand that seven societies have been added to the list. The increase affords some measure of the steady and healthy progress of scientific thought in Great Britain. As usual, the entries are grouped conveniently according to subject, and in each group there is a further subdivision into societies in London, the provinces, Scotland, and Ireland Under each entry is included the address, officers, meetings, conditions of membership, and publications of the society or institution in question, and in many cases the titles of papers read during the session 1923–24 follow Valuable summaries of the work during the year of such public institutions as the Royal Observatory, Greenwich, the National Physical Laboratory, and Rothamsted Experimental Station are also given Our thanks should be added to those of the publishers to the officials whose replies to requests for detailed information have made it possible to issue such an "official" volume It was probably too late for insertion that the new address of the Royal Dublin Society at Ballsbridge, Dublin was announced.

In turning over the pages, we have found the British Photographic and the British Cast Iron Research Associations (the former not indexed), but none of the score or so of the remaining industrial research associations The volume as it stands is, however, a valuable work of reference, which all who would keep in touch with scientific movements in the British Isles would do well to have at hand.

Auxiliary Tables of the Survey of India. Fifth edition. Revised and extended by Dr J de Graaff Hunter. Part 1: Graticules of Maps Pp 25 (R. 1=2s) Part 2: Mathematical Tables. Pp xiii+89 (Rs. 2=4s) Part 3: Topographical Survey Tables. Pp. xxi+52. (Rs. 1 8=3s.) (Dehra Dun: Trigonometrical Survey, Part 1, 1921. Part 2, 1924. Part 3, 1923.)

THE work of the Survey of India, especially in the domain of geodesy, has a world-wide reputation. The first edition of these tables, which are intended to facilitate calculations connected with survey operations of all kinds, appeared so long ago as 1868 They have more than once been copied and adapted by the surveys

of other countries, though, of course, they are primarily intended to apply to the methods and scales used by the Survey of India.

Part 1 contains tables for the projection of maps falling within the latitudes embraced by India: on the polyconic projection, which is that employed for the larger scale topographical maps, on the modified secant conical for small scale and general maps; and a table for the projection of the sheets of the *Carte International*, on the millionth scale, of which India has produced so many sheets. Part 2 displays a series of mathematical tables in general use in survey operations, also metrical equivalents; mathematical and physical constants, geodetic data (fundamental co-ordinates adopted by the Survey of India), and, at the end, a few pages of useful mathematical formulæ. Part 3 comprises a set of tables covering all the ground required by the topographical surveyor in his triangulation and astronomical work in the field.

These tables are a considerable advance on the previous editions, and Dr. Hunter deserves great credit for the way in which they have been presented. They have been prepared most carefully so as to assist in the solution of almost any problem with which the surveyor is likely to be confronted. The plan of publishing each part separately has added very much to their convenience for use in the field or office.

Part 4, Geodetic Tables, is under compilation, and may shortly be expected; while Part 5, explaining the forms and formulæ in use in the Survey of India, is in contemplation. The parts already issued contain full explanations of the tables, and also, in most cases, examples showing how the tables are used in practice.

H. L. CROSTHWAIT

Travaux pratiques de physique générale exécutés à l'Institut de Physique de la Faculté des Sciences de Strasbourg en vue du certificat d'études supérieures de physique générale. Par Prof. H. Ollivier. Première série: Sujets de 45 manipulations, réparties en 30 séances de 4 heures. Pp. 104+9 planches. (Paris: J. Hermann, 1924.) 12 francs.

PROF. OLLIVIER'S "Cours de physique générale" has already been the subject of favourable notice in these columns. The present volume on advanced practical physics maintains the high standard we have been led to expect from the professor of physics of the University of Strasbourg. It forms the first part of a treatise on the subject, and contains an account of those experiments which are repeated each year by all students attending the advanced course. It is assumed that the student has already attended an elementary laboratory course, is familiar with the theory of many of the instruments, and has a fair knowledge of mathematics. Classical experiments predominate in this first volume, and the apparatus used is carefully constructed and tested. Many of the instruments described are expensive, and students are expected to use them with the utmost care and to obtain results of a high degree of accuracy.

The experimental hints and cautions given in the text are most valuable, and all teachers will appreciate the "recommendations générales," prominently displayed early in the course: "Il ne faut toucher avec les doigts ni les parties graduées des appareils, ni les verniers, ni les poids de précision, ni les pièces optiques: lentilles, miroirs, nicols, lames quart d'onde, etc." Amongst the experiments we note with special interest Rowland's method of determining the mechanical equivalent of heat, the use of the stroboscope, photography, including photography in colours by the Lumière process (in this case no directions are given), a study of elliptically polarised light (arranged by M. G. Foex), magnetisation of an iron ring using a fluxmeter, and the behaviour of a three-electrode lamp. A novel and interesting feature in a text-book of practical physics is the series of nine plates containing excellent photographs of the Institute of Physics of the Faculty of Sciences of Strasbourg and of the apparatus arranged for experimental work in the laboratories.

H. S. A.

An Introduction to the Study of Cytology. By Dr. L. Doncaster. Second edition. Pp. xiv + 280 + 24 plates. (Cambridge: At the University Press, 1924.) 21*s*. net.

IT is not always that literary ability and scientific method are wed together in sufficient degree to produce a sound scientific text-book which is, at the same time, of literary merit. In recent years few famous biologists have possessed both these qualities in greater degree than the late Prof. Leonard Doncaster. It is, therefore, with special pleasure that we welcome the appearance of a second edition of his well-known book on "Cytology."

A monograph on any highly specialised branch of study has one great advantage over a work produced by the collaboration of a number of authors in that it possesses a greater unity of purpose, as the conception of a single mind, than could be produced by the most successful team work. In this respect all must admit that Prof. Doncaster's book is pre-eminent. But to maintain this quality becomes a most serious difficulty to the editor of a posthumous edition. This Mr. Grey has admirably overcome, and, although introducing much new and useful material, has in no way detracted from the arrangement and theme of the book as a whole.

The book would have been improved, perhaps, if more space had been given to the recent extensive advances in our knowledge of the cytoplasmic inclusions. Further, we cannot help feeling that much too little space is devoted to a consideration of the various types of cells of the soma of higher forms, for almost the entire book is concerned chiefly with the reproductive processes of gametogenesis, fertilisation, and segmentation.

The production of the volume is excellent, and we are pleased more especially with the illustrations. We consider the edition a well-written and instructive text-book for the student and research worker.

F. W. ROGERS BRAMBELL.

A School Chemistry. By O. J. Flecker. Pp. viii+238. (Oxford: At the Clarendon Press; London: Oxford University Press, 1924.) 3*s*. 6*d*. net.

AMONG the minor compensating advantages of the War period was the check given to the ever-rolling stream of text-books on elementary science, but now that paper and printing are less costly, the tide appears to be rising again; let us hope it will not overwhelm

us. The young and aspiring teacher may be commended for his zeal in writing a text-book for his own use—authorship invariably impresses a literary headmaster and a governing body—but it is a question whether his time would not be better spent experimenting in the laboratory and in keeping well abreast of modern developments. It is another matter if he has something really novel to say, or some new method of arrangement or presentation Unfortunately, however, originality seems to be somewhat elusive since the salad days of Ostwald, Alexander Smith, and Armstrong, and the present little work, like scores of others, does not excel in this respect The book has its merits; it is well written and particularly well spaced; the explanations are clear, and there is very little to criticise on the score of choice of experiments or of accuracy (but *any* chloride would not do instead of salt for making hydrogen chloride, p 94). The main defect is a too strict adherence to the old-fashioned, cookery-book style, the pupil who believes all he is told in this book, and performs religiously the rites prescribed, will certainly learn much that is useful and interesting, but they will not help him to acquire or develop the scientific habit of mind, a possession of far greater value than a passive knowledge of the *minutiæ* of chemical change.

Contributions from the Jefferson Physical Laboratory and from the Cruft High-Tension Electrical Laboratory of Harvard University for the Years 1922 and 1923. Vol 16 47 papers, unpaged. (Cambridge, Mass.. Harvard University, n.d.) n.p

THIS volume covers a rather longer period than is indicated in its title, the earliest paper dating from February 1921 and the latest April 1924. Ten of them are by Prof. Bridgman, and deal with the properties of materials under high pressure, and several of these have been noticed in our columns Eleven others are due to G L. Clark, National Research Fellow, and Prof. W. Duane, and deal mainly with X-rays and their use in crystal analysis. In their method of investigating crystals the continuous spectrum of X-rays between 0·12 and $0{\cdot}89 \times 10^{-8}$ cm. is utilised, and this allows of the use of an ordinary X-ray tube with tungsten target run at a high voltage. The substance examined may be a single crystal or a powder. The wave-length of a ray which is reflected at a given angle from the material is calculated from the quantum equation $Ve\lambda = hc$, where V is the least voltage applied to the tube which will cause it to emit the line λ, e is the electronic charge, h Planck's constant, and c the velocity of light. The tube being run from a storage battery, V can be determined accurately. Prof. Lyman contributes three papers on a new vacuum spectrograph and the extreme ultra-violet spectrum.

The volume maintains the high standard established by its predecessors and shows that Harvard believes in extending as well as imparting knowledge.

Beach Grass. By C. W. Townsend. Pp. xii+319+42 plates. (Boston, Mass.: Marshall Jones Co., 1923.) 3.50 dollars.

THE reader who expects under this title to find a dissertation on *Psamma arenaria*, the marram grass of the coasts of the British Isles, will be disappointed, for the plant is scarcely mentioned. But the book is well worth reading. It is a breezy, refreshing account of many aspects of Nature on the sand-dunes that form the coast line in the neighbourhood of Ipswich, Essex Co., Massachusetts, U S A. The author is a naturalist in the widest sense of the word, and has here set down a number of observations, illustrated by some admirable photographs, that will interest alike the serious student of physical geology, the ornithologist, the forester, and indeed all whose scientific tastes take them into the open air. The description of the ice-bound sand-dune coast, and the effects of frost both on the shore and on the sea itself, and the bizarre scenery produced and most successfully illustrated, are truly wonderful In the chapters dealing with birds, biologists will find some shrewd remarks on sexual selection, and interesting accounts of the courtship of many species of birds Incidentally there are quoted authentic examples of the economic value of several birds of prey and of some of the insectivorous birds The book would perhaps be of more direct use to the British reader if the scientific names of the birds were inserted . the popular American names are not very familiar on the eastern side of the Atlantic

Reason and Morals: an Enquiry into the First Principles of Ethics By Dr Israel Levine. Pp xi+177. (Glasgow: MacLehose, Jackson and Co , London: Simpkin, Marshall and Co , Ltd , 1924) 6s net

THE author received the degree of D Litt from the University of Glasgow for this thesis, and though primarily dealing with a subject of philosophy, it is of peculiar scientific interest The moral law is generally held up to wonder and veneration as something utterly unintelligible on ordinary scientific principles, indicating a supernatural origin and bearing witness to a divine purpose in individual lives Dr. Levine, in a clear and trenchant argument, sweeps this whole conception away. The moral law is shown to be the simple condition on which human society can exist. Without morals common life is impossible, and without common life the survival of the human species is impossible The existence and maintenance of social life are the inevitable expression of the life-impulse itself. The essay concludes with a brief historical survey, in which it is claimed that the rational tradition in moral theory has received in modern times its complete vindication in the discoveries of psychology.

Die Grundgedanken der Machschen Philosophie: mit Erstveröffentlichungen aus seinen wissenschaftlichen Tagebuchern. Von Prof. Dr Hugo Dingler. Pp 106. (Leipzig . J. A. Barth, 1924) 3 gold marks.

AN excellent short account of the leading thought and ground-principle of the most philosophically minded of the German physicists When only fifteen, he had read from his father's library Kant's "Prolegomena" and Fechner's "Tagesansicht," and he seems even then to have formed a fixed resolution to eschew metaphysics and follow in all his researches a pure inductive method. He had throughout his life an almost English aversion to apriorism and to transcendental systems of philosophy. The book contains a most interesting selection from his note-books from 1880 to 1882 with memoranda for his "Mechanik." It recalls the "Common-place Book" of our own Berkeley.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Future of the Meteorological Office.

In the note on Mr C J P Cave's presidential address to the Royal Meteorological Society (NATURE, January 31, p. 168) Mr Cave is quoted as saying, "It is true that there is the Meteorological Office, but its position at the present time is an unfortunate one, its future is uncertain In the past the Meteorological Office was directly under the Meteorological Committee, which administered a Government grant. Soon after the War, the Office was placed under the Air Ministry It seems a grave anomaly that the Meteorological Office, which deals with problems of the greatest importance to many Government departments and to many public bodies, should be solely under the direction of the Air Ministry, more especially when there is in the Department of Scientific and Industrial Research a very suitable body under which it might have been placed"

Although I am sure Mr Cave would not wish this to be taken as anything more than his own personal opinion, I must ask you to allow me to say that I do not share it Far from the Meteorological Office being in an unfortunate position, it is fortunate in being able to command, under the Air Ministry, many facilities which no other Government department could give The well-organised wireless service of the Air Ministry, with its powerful station at Kidbrooke, is available for the exchange of those wireless messages on which national and international meteorology now depends. Aeroplanes are placed at our disposal to obtain observations from the upper air, and this would be quite impossible if we were not closely connected with the Royal Air Force and the Royal Aircraft Establishment at South Farnborough

I do not understand what Mr Cave means when he says "its future is uncertain." It is true that the Meteorological Committee formerly administered a Government grant, but that grant was only 20,000*l* before the War, while the meteorological expenditure now borne on Air Votes is more than 100,000*l* The Air Ministry necessarily exercises financial supervision over this expenditure, but I have no reason whatever to complain of the result In so far as the Treasury intervenes, this is an inevitable concomitant of the appropriation of money from public funds and is applicable to all voted services alike, whether administrative or scientific.

Flying, especially civil flying, is so dependent on a good meteorological service that if the Meteorological Office were not under the Air Ministry, there would have to be a separate meteorological service for aviation Only those who have had to organise the existing complicated meteorological service for aviation with its thirteen stations on aerodromes and hourly messages along the Croydon-Continental routes can realise the close connexion necessary between the Meteorological and other departments of the Air Ministry

Because the Meteorological Office deals with problems of the greatest importance to many Government departments and to many public bodies, the Meteorological Committee has been retained to advise the Air Council on matters relating to the Meteorological Office This Committee, on which there are representatives of the Royal Society, the Royal Society of Edinburgh and six Government departments, is by no means without influence on the policy of the Meteorological Office The Committee takes special interest in the scientific work of the Office, and one representative of the Royal Society is ex-officio vice-chairman This alone would be a guarantee that the scientific work is well maintained. As a matter of fact, we have more staff engaged on purely scientific work than ever before, and I am proud of the number of papers which are published yearly by my splendid scientific staff

After four years' experience as Director of the Meteorological Office under the Air Ministry, I am convinced that we could not do our work so well under any other department of Government, and I should be very sorry to have to return to a grant-in-aid

High Energy γ-Ray from Thorium Disintegration Products.

In the light of the standard measurements of the β-ray spectra of radium-B and -C by Ellis and Skinner (Roy Soc Proc, A, vol 105, p. 60, 1924) it was thought advisable to remeasure the spectra of thorium-B, -C, and -D This has been done, using the now well-known focussing method, and the results will be published in due course The purpose of this letter is to direct attention to two lines of high energy, namely, 2 55 and 2·62 million volts, with a possible third of slightly greater energy. The detection of these lines has been made possible by the preparation of thorium-B sources of greater strength than usual. There is no doubt of their existence, as they appear very clearly and sharply on the photographic plate. What is most remarkable is the fact that these lines correspond to the conversion of a γ-ray of energy 2·64 million volts in the K and L levels of an atom of atomic number 82 or 83, despite the fact that their energy is some twenty-eight times as great as that of the K level of an atom of that atomic number. This shows that the quantum relations hold for these high energy values in exactly the same way as they have been shown to do for the lower ones From an examination of the plates, it is seen that these lines lie beyond the region of the continuous background, and this fact may be of importance in atomic theories. Another point of interest is that there appear to be no lines between these and those of an energy of about 0 8 million volts D H. BLACK

Touch and Sight *v.* The Microscope in Wool Classing and Sorting.

Not only do the fleeces from distinct breeds of sheep vary very considerably, but also, almost without exception, each individual fleece is made up of from three to seven or eight "qualities" of fibre

To the non-technical reader the term "quality" is something of a mystery, so it will be well clearly to define this term before proceeding further. This term has no reference to the "fibre-stuff," but refers principally to the fibre diameter. Thus, if q = quality number and d = fibre diameter in the fraction of an

inch, the following equations link up "quality" and "fibre diameter".

$$\text{Log. } a = \frac{1}{1\cdot6}(\log 1\,52 + \log d), \quad . \quad . \quad (1)$$

or

$$d = \frac{1}{1\,52\,q^{1\cdot6}} \quad . \quad . \quad . \quad (2)^1$$

Taking (1), with a 58's quality, the following result is obtained

58's quality = 1/1000 in diameter

Taking (2), with a fibre of 1/1000 in diameter the following result is obtained:

1/1000 = 58's quality

In List I the relationships between quality numbers 28's to 100's and fibre diameters are given

LIST I.—RELATIONSHIPS BETWEEN BRADFORD QUALITY NUMBERS AND FIBRE DIAMETERS IN FRACTIONS OF AN INCH

μ (1/1000 of m.m.)	Bradford Quality Number	Diameter Reciprocal by Formula
		in.
80·89	28's	314
65·30	32's	389
54·04	36's	470
42·69	40's	595
39·19	44's	648
36·50	46's	696
34·14	48's	744
31·95	50's	795
30·02	52's	846
28·25	54's	899
26·65	56's	953
25·23	58's	1007
23·86	60's	1064
21·52	64's	1180
19·54	68's	1299
18·66	70's	1361
15·06	80's	1686
12·48	90's	2034
10·54	100	2408

The connexion between the quality number and the fibre diameter is now quite evident, but the question at once arises as to what the quality number really represents

The quality number represents the number of hanks of 560 yards each to which one pound of the particular wool in question may be spun. Thus, 58's quality conveys to the spinner the information that

$$58 \times 560 = 32{,}480 \text{ yards}$$

may be spun from one pound of this wool. Thus, in a sense, the quality number represents the fineness of yarn (thread) which may be spun from any wool under consideration. In actual practice it is agreed that, broadly speaking, the quality number is rather greater than the corresponding length of thread. Thus, a 58's quality wool would not, as a rule, be spun to a count finer than 50's, that is:

$$50 \times 560 = 28{,}000 \text{ yards per lb}$$

Thousands of wool-classers[2] in Australia and elsewhere, and of sorters in Bradford and elsewhere, are daily classing or sorting fleeces of wool into the respective "qualities," and one or two interesting questions arise with reference to this work. In the first place, Is a sorter always consistent in his sorting? Does he always class the finer wool, say in a typical merino fleece, as 80's, the medium as 70's, and the coarse as 64's? And if he is found to be doing this according to the given equation to-day, did he make the same classification last year, and will he be making the same classification next year—say, as a test case, after six months away from the sorting table? More important still, will the wool-sorter in Bradford sort his fleeces into the same qualities that the Australian wool-classer would make, and will he be equally consistent in his sorting?

The writer has recently had the opportunity of carrying out certain classing and sorting tests in Australia, and later in Bradford, which, at least in part, answer these questions. On Bundure Sheep-station (New South Wales) the wool-classer was asked to select three typical qualities of wool, 68's, 64's, and 60's. Later, these were measured under the microscope, and upon these measurements the "frequency curves" shown in Fig. 1 were constructed and the "average diameters" of the three qualities of wools ascertained. It will be noted that the

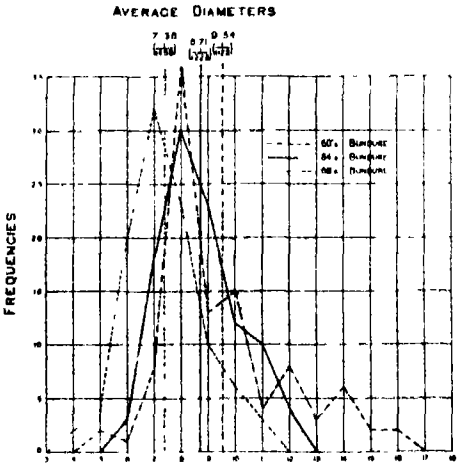

FIG. 1.—Bundure "Classings."

microscope almost exactly confirms the wool-classer's relative qualities, but that so far as coincidence with List 1. is concerned, the Australian wool-classer is almost a quality lower than the list.

Later, Camden Park (Sydney) merinos were submitted to a wool-sorter in Bradford, and he made of these wools three qualities, 80's, 70's, and 64's. Again, on the sorting being tested by the microscope, it is found that the sorter is quite consistent with his own qualities, the frequency curves being given in Fig. 2. On comparing Figs. 1 and 2, however, it is found that, following the microscopic measurements, approximately the same fibre diameter (1/1400 in.) is stated as 68's by the Australian wool-classer and as 80's by the Bradford wool-sorter. On comparing the 64's, however, it will be noted that the Australian wool-classer's 64's (Fig. 1) has a fibre diameter of 1/1122 in., while the Bradford wool-sorter's 64's (Fig. 2) has a diameter of 1/1311 in., *i.e.* finer than the Bundure 64's (1/1228 in.). Both are finer than would be expected from List I., and no doubt indicate that just as the temperature of the hand before estimating the temperature of a liquor may affect the estimate, so may touch and sight testing be affected by the exercising of these faculties just previous to the quality estimates in question.

These differences may further be explained as follows. The Bradford sorter is possibly sorting his wools into rather higher qualities than those prevailing in pre-War times. Again, the amount of "yolk"

[1] See "Woollen and Worsted Spinning," Wilkinson's Rule, p. 231 (Messrs. Cassell and Co.).

[2] "Classing" is the term applied to the estimation of the "quality" of the whole fleece, "sorting" is the term applied to the separation of the several qualities in one fleece.

(grease, etc) in the fibre varies with different wools, and in the case of these two wools was approximately:

Bundure . 50 per cent loss on scouring,
Camden Park . 60 per cent loss on scouring.

Thus, as the micro-measurements were made after clearing with ether and the classing or sorting carried out "in the grease," certain of the differences

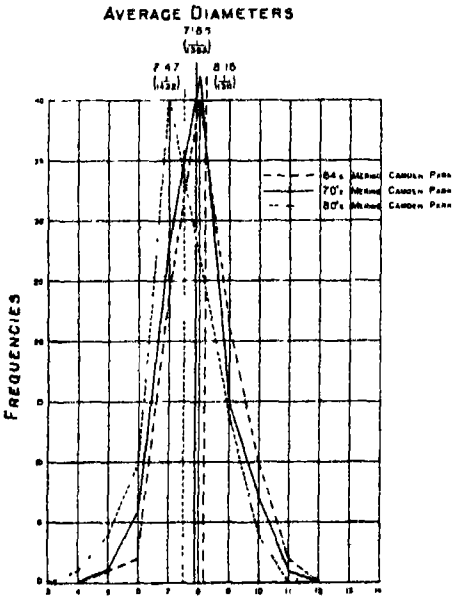

FIG. 2.—Bradford "Sortings."

observable may be explained. Broadly speaking, the following conclusions are to be drawn:

1. Wool-classers are very consistent in their "quality" estimations,

2. Wool-sorters are very consistent in their "quality" estimations,

3. Wool-classers as against wool-sorters and vice

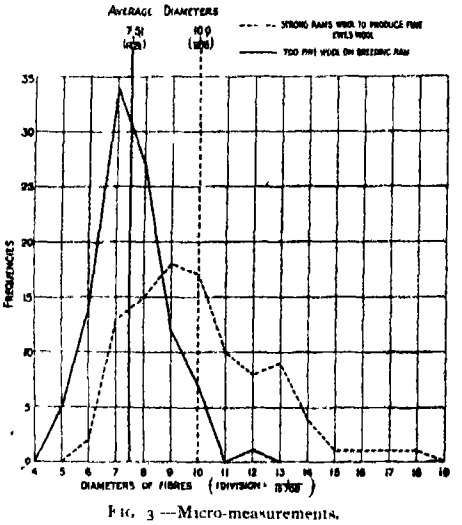

FIG. 3.—Micro-measurements.

versa are broadly consistent in their "quality" estimations,

4. Wool-classers in Australia as against wool-sorters in Bradford show small differences in their "quality" estimations—not always unimportant—when contrasted with one another;

5. Varying trade standards and varying conditions of the wools being classed or sorted affect the quality estimation;

6. Micro-metrical measurements may almost always be made under similar conditions, so that such "quality" estimations should be quite consistent;

7. Owing to the impossibility of examining more than a very few of the fibres under estimation (100 tests each in Figs. 1 and 2) the micro-metrical estimation is liable to give very erroneous results unless the test samples of fibres examined are very carefully selected and are truly representative of bulk.

It would thus appear that, under normal conditions, the work of the well-trained wool-classer or wool-sorter is trustworthy and that, broadly speaking, micro-metrical sorting will not be markedly better, and, if not carefully undertaken, may be worse.

An interesting case, however, arises when one wool happens to be, say, a 70's quality because the fibres are very consistently 1/1300 in. in diameter, and another wool is a 70's quality because many fibres above 1/1300 in. in diameter are balanced by others below even 1/1000 in. Such a case as this is partially in evidence in Fig. 3. Here are given the frequency curves for two wools specially selected by a noted Australian breeder as typical of a wool too fine (70's) and a wool about right (60's) for selected rams. The two curves reveal an astonishing difference in the "make-up" of the respective wool staples, of which the breeder was totally unconscious and which neither wool-classer nor wool-sorter would be likely to make note. It should also be noted that the narrow bases of the curves in Fig. 2 as against the broad base of at least one of the qualities in Fig. 1 might also tend to confuse the "classer" and the "sorter." Little has been done in such "correlating" as that treated here, but the subject is full of interest, and may prove to have most important bearings upon the selection of rams for breeding purposes both at home and in the Overseas Dominions. In the Textile Industries Department of the University of Leeds extensive ranges of typical Merino and British pedigree wools are being dealt with, and it is hoped that eventually (*a*) definite standards and (*b*) accepted methods of testing may be adopted throughout the wool industry both at home and abroad.

The Theory of Hearing.

IN NATURE, April 22, 1922 (vol. 109, p. 518), I pointed out that a series of clicks from a toothed wheel speeded up or down or by the voice is heard as a rising or falling tone and not as a noise or a jumble of tones. This fact contradicts the resonance theory of the mechanism of the cochlea.

The theory has now received a blow in the experiments of Dr. Harvey Fletcher at the Research Laboratories of the American Telephone and Telegraph Company and the Western Electric Company in New York (*Phys. Rev.*, 1924, xxiii., No. 3). The fundamental and a large number of harmonics can be eliminated from a compound tone without changing the pitch of the tone. A high-quality telephone system was used about which it was known that the sound coming out of the receiver was a faithful copy of that going into the transmitter. Electrical filters were introduced so that any tones could be eliminated. The character of the results was judged by three persons familiar with music, who agreed in every case. Typical experiments are the following:

Sound.	Pitch.	Eliminated components.	Eliminated frequencies.	Pitch change.	Quality change.
Voice *ah*	145	F	0 to 250	None	Inappreciable
		F+1 to 2	0 to 500	,,	Small.
		F+1 to 4	0 to 750	,,	Large
		F+1 to 7	0 to 1250	,,	Very large.
		F+1 to 9	0 to 1500	Uncertain	Noise
		6 to ∞	1000 to ∞	None	Small
		3 to ∞	500 to ∞	,,	Large.
		F −1 to 2 −6 to ∞	0 to 500		
			+1000 to ∞	,,	Very large.
Clarinet	259	F	0 to 500	,,	Large.
		F+1 to 2	0 to 1000	,,	Very large
		F+1 to 4	0 to 1500	,,	Non-musical.
		7 to ∞	2000 to ∞	,,	Large
		2 to ∞	750 to ∞	,,	Pure tone with no clarinet quality.

The work of Wegel and Lane (*Phys Rev.*, 1924, xxiii., No 2) and Fletcher (*Phys Rev.*, 1920, xv. 513) has shown that the hearing mechanism displays a non-linear response to external forces The character of the sensation when two tones are acting together on the ear varies considerably with the relative frequency and intensity values (Wegel and Lane) According to their dynamical theory, the vibrations pass along the basilar membrane and are shunted through narrow regions of the membrane at points depending on the frequency. The dynamic theory is simply a modified resonance theory.

Any resonance theory fails to explain Fletcher's experiments. When, for example, the fundamental is removed from a clarinet tone, there is no change in the pitch of the tone According to the resonance theory a sensation of tone corresponds to the vibration of a region of the fibres of the basilar membrane and vice versa. Here vast regions of the fibres may or may not vibrate without altering the sensation of pitch. The only change is one of quality Fletcher attempts to get around the difficulty by supposing that subjective tones—summation and difference tones—are introduced (!) mechanically in the cochlea into the stimulus that is sent to the brain For example, the presence of the tones 500 to ∞ in the clarinet experiment produces a sensation of a tone of the same fundamental pitch as 259 to ∞ with only a difference in quality, because these tones arouse the missing tones in the cochlea

This is a responsibility too heavy to be accepted on the basis of a hypothetical resonance analysis of the basilar membrane The responsibility becomes much less when the fibres of the membrane are regarded only as supporting and stiffening fibres not tuned to resonate. The result then becomes identical with my deformation theory reported in NATURE, April 26, 1924 (vol 113, p. 605) According to this theory, the basilar membrane alters the linear movement of the stapes into a change of form in three dimensions. Every external vibration produces a pattern deformation of the membrane. This pattern is communicated to the brain. A single vibration of a clarinet tone produces a definite pattern in three directions on the basilar membrane. The mental quality of the clarinet tone represents this pattern. When this vibration is repeated regularly, the clarinet quality appears to be based on a tone of definite pitch. Whether a tone of this pitch or of any other pitch is physically present in external vibrations or not, a fundamental will be heard as the loudest tone, the pitch of which is determined by the frequency of the repetitions.

Fletcher's experiments are an illustration of what occurs constantly in song. Many, perhaps most, vowels have no fundamental vibrations (NATURE, Jan. 13 and 20, 1921, pp. 632 and 664). They are produced by a series of isolated puffs which set the vocal cavities in vibration. Such vowels consist solely of higher tones than the one that is sung Yet, although the fundamental is lacking physically, it is heard as *the* tone of the voice. The physically non-existent tone is exactly the one—and the only one—indicated by the music. It is the tone intended to be sung, and is the one heard as a tone; the other tones—in this case all the tones that exist physically—are heard only as timbre or quality.

The work of Willis, Hermann, and myself on the vowels is now supplemented by the work at the New York laboratory All of it flatly contradicts the resonance theory. The simple facts of the accelerated toothed wheel and of portamento speech, however, ought to have been enough to convince any one. E W. SCRIPTURE.

University of Vienna.

The Ages and Masses of the Stars.

THE very interesting correspondence between Mr. Schumann and Dr Jeans in NATURE of January 24 has not touched on one of the most difficult questions, raised by the brilliant paper in which Dr. Jeans makes out such a strong case for extending our time-scale for the life of a star to some 10^{13} to 10^{14} years. The problem is simply how we are to account for the existence of uranium and thorium

As is well known, uranium has a half-life period of 6×10^9 years Therefore, even if the whole sun had consisted initially of uranium, there would barely be 2 kilograms left after 6×10^{11} years A great deal more than this exists on the earth alone Hence, either the life of the sun and earth must be much less than 6×10^{11} years or we must make the *ad hoc* assumption that uranium is being formed or at any rate prevented from disintegrating The temperature and pressure inside the sun are much too low to affect a reaction, the energy of which is so great as the energy of formation of radioactive substances.

A solution may be found if one admits the coalescence and annihilation of protons and electrons, for then, of course, radiation with quanta of energy $1{\cdot}66 \times 10^{-3}$ would be available. That this might photosynthesise uranium nuclei, though of course possible from purely energy considerations, scarcely seems plausible when one remembers that these complicated structures contain 238 protons and 146 electrons But it is not impossible that it might cause α-particles, which are presumably common in the interior of stars, to combine with lead and the heavier radioactive elements. On such a theory presumably the non-radioactive substances would be assumed to be built up in the same way

The basis of this explanation, however, the seductive hypothesis that protons and electrons may coalesce and be annihilated, is not without difficulties of its own The process in question presumably would occur when a proton and electron meet under certain peculiar conditions The frequency of such encounters must almost certainly depend upon the density and, to a less extent, on the temperature. The position would be much clarified if it could be shown from astronomical evidence that the evolution of energy per unit mass varied in the appropriate way with the density and temperature

These or similar speculations, which become inevitable if one accepts the extended time-scale, had therefore perhaps best be postponed until Dr. Jeans's theory has been further tested. They would be avoided, of course, if it could be shown that the loss of ordinary atomic mass under the influence of radiation pressure is much greater than the radiative mass emitted. It is difficult to make any convincing

estimate, but should it prove to be so it would immediately reduce our time-scale and relieve us of the necessity of entering upon speculations such as those touched on above

On the Hardness of Manganese Steel.

NOTWITHSTANDING its extraordinary importance, the discovery of the 13 per cent manganese steel, made by Sir Robert Hadfield more than forty years ago, has scarcely been elucidated regarding its most striking point, namely, the extremely high resistance to wear and tear, or the fact that the non-magnetic manganese steel, while comparatively soft in itself, offers an enormous resistance to a working tool

It is natural to assume that this resistance is to be explained in the following way.[1] The state of the iron in the manganese steel being that of the non-ferromagnetic γ-iron, stable at high temperature but unstable at ordinary temperatures, a mechanical stress is likely to cause the transformation into the ferromagnetic α-state, stable at low temperature This is in conformity with a general law of physical chemistry, exemplified by the well-known case of mercury iodide the yellow modification, persisting at ordinary temperature in an unstable condition, is transformed by mechanical stress into the red modification, stable at low temperature In other words the high resistance is explained by the assumption that mechanical work transforms the relatively soft Mn- austenite (γ-Fe) into martensite (α-Fe), known to be extremely hard From this view, if correct, it follows that mechanical work will at least partly transform the non-magnetic manganese steel into the ferromagnetic α-condition

Some time ago the correctness of this conclusion was tested at this Institute by Dr A. Westgren on a specimen, sent by Sir Robert Hadfield, of manganese steel which had been subjected to a tensile test

On X-ray analysis, however, no lines characteristic for α-Fe could be detected even in the contracted part of the specimen In view of this negative result, the following experiment, lately performed, seems to be of interest.

A small steel magnet needle (about 3 × 0·5 × 0·1 mm.) was fastened to one end of a thin silica fibre, so as to be suspended in a vertical position On approaching the sharp corner, or edge, of a Hadfield manganese (Era) steel specimen, it was not possible to obtain any sensible attraction of the needle—in conformity with its non-ferromagnetic character. On the other hand, a small drilling of the same steel (say 1·2 × 0·4 × 0·1 mm.) fixed at the end of a glass capillary, when brought near the needle, revealed a considerable attraction, or repulsion, proving the *drilling to be plainly ferromagnetic*, and thus even permanently. The objection being possible that the ferromagnetism might be caused by steel particles given off by the drill used, metallic shavings were obtained by using sharp quartz edges, and also a slow rotating alundum disc, in both cases the shavings were found to be distinctly ferromagnetic

Since it had been established in this way that the shavings have the magnetic characteristics of martensite, they were submitted to X-ray analysis by Dr. Westgren However, no lines of the α-state could be detected The reason probably lies in the fact that the α-lines are sharp only for a comparatively pure α-iron lattice, and rather blurred for the α-solid solutions, if in addition the α-portions occurring are few in number and very small, the analysis method developed as yet, is not sensitive enough to detect them. It may be considered as established that the difficulty in working non-magnetic manganese steel, is due, at least partly, to its partial transformation into martensite

A Stroboscopic Method of Determining Surface Tension of Liquids.

OF the various methods of determining surface tension of liquids, the method of ripples is free from all surface influences Lord Rayleigh, Dorsey, Grunmach, Kalähne and others have determined the surface tension of water by this method Grünmach applied the same method in determining the surface tension of some of the molten metals, but the main difficulty was that of observing the ripples properly to measure the wave lengths exactly, and the accurate estimation of the vibration frequency of the exciting fork Unless the stroboscopic arrangement is perfect, there is always an uncertainty in the determination

FIG. 1

of λ accurately, and as λ^3 is to be taken in the calculation, a slight variation in the value of λ affects the final value

We have, however, devised a method by which the stroboscopic arrangement is completely satisfactory. By fixing a fine edge to the prong of the exciting fork, and observing the reflection of this edge on the surface of the liquid at Brewster's angle (for water it is 53° 6′) fine teeth appear on the reflected image of the fine edge These teeth remain absolutely stationary so long as the vibrations of the fork remain constant The tips of the teeth are extremely sharp and stand a good deal of magnification (Fig. 1). The measurements of λ, therefore, could be made accurately The excitation is produced by a fine needle soldered to one end of this edge, the needle dipping only about 0·25 mm. below the liquid surface. The ripples are scarcely visible on the surface

The result given by this simple apparatus is satisfactory, namely, 74·1 in the case of clean distilled water The vibrations of the tuning-fork are also recorded along with a standardised seconds pendulum, so that the frequency can be ascertained with great accuracy up to the second place of decimals. A slight touch of grease at once increases λ considerably, as has been pointed out by Lord Rayleigh.

The Permanence of Substance.

By Sir JOSEPH LARMOR, F.R.S.

IN Victorian times the atoms of matter were described by Clerk Maxwell, in picturesque and weighty phrase, as the "foundation stones of the material universe." It was believed that an æthereal medium for physical intercommunication in the cosmos was essential: and if so, material systems could not arise as other than mobile structures inhering in that universal medium. The standard illustration (for that was its true function) which went far by visual experiment to give vitality as well as precision to this general doctrine, was the Kelvin formulation of vortex atoms, based on Helmholtz's advances in the exact hydrodynamics of ideal perfect fluid, and lying in the natural succession to the brilliant but often fantastic gropings after vortical imagery by Descartes. The force of the illustration lay in the certainty that in the ideal pervading medium such vortex structures could not be wiped out, must be indestructible for ever. The ultimate atoms of matter, which stimulated the investigation of these vortical ring structures by way of analogy, have now been pushed back, first in theory and afterwards far more precisely by experimental discovery, to the electronic constituents of the chemical atoms.

If there is an æther, matter must be of necessity atomic, the possible variety of atoms being restricted to the limited number of types of suitable structure that are dynamically stable. and conversely, if matter is found to consist actually of self-contained atomic structures, this central fact is either evidence for a universal æther in which all matter subsists, or else must remain wholly inexplicable, perhaps even inscrutable. Such would be the modern version of the great argument of Democritus, on atoms and the void.

On the other hand, in extreme modern developments of the idea of relativity, the material universe seems to have no "foundation stones." An ultimate atom of matter is not there describable as an essential structure at all, such as can be explored, of course only partially, yet to an increasing degree which becomes adequate for more and more scientific purposes. It usually appears as nothing but a local aggregation of electric charge, held together by unknown internal constraint which is assumed not to disturb other relations. It can thus be liable to dissolve itself into pure motional energy by fusion with opposite charges; and the fact that the measures of mass and energy are modified in the same way by change of the frame of reference lends plausibility. The end of the cosmos would be the vanishing of matter: its beginnings must be on every scheme inscrutable.

It seems to be mainly with a view to elegance and completeness in the algebra that the electronic nucleus is thus introduced merely as a local aggregation of electric charge with some permanent law of volume-density. At a later stage it became recognised that internal forces are needed to hold it together; and whatever they may be they must not interfere with its necessary relativity as a whole as regards uniform translatory motion. They seem to be disposed of by being classed in the exposition as an unknown part of the stress-tensor of the field. Thus this procedure can be in no respect an improvement on the classical method which it claims to supersede, of regarding an electron as a structural singularity unknown except so far as it is defined by increasing knowledge of the field that is physically attached to it by its very constitution. Even in pure spatial analysis of differential geometry a singular pole is approached through the influence it sheds around the algebra never gets into the inside of it, so to say. That is the classical way, and can be held to be the correct scientific method, of approach to the properties of the unknown permanent electron or atom. The occasional denial of it seems possibly to be linked up with a metaphysical doctrine[1] that all natural law is nothing more than a manifestation of the *quasi*-geometric qualities of a fourway continuum named space-time, so that a complete exploration throughout it, by continuous spatial analysis without inherent unexplored poles, must be the aim of physical theory. The alternative view is that the infinitely little transcends human grasp by involving just as great inherent complexity as does the infinitely large, though both can be approached and annexed, with increasing completeness, to our scientific schemes, by virtue of transcendental relations of mind to matter which lie at the root of all possibility of knowledge or scientific formulations.

In further illustration of the contrast of methods, these hypothetical internal stress-forms the rôle of which is to hold a local distribution of electric density together, and so constitute an electron, may be more closely considered. They are now often referred to as the "forces of Poincaré," because he found out that for a shell model of the electron they can be formulated simply as an isotropic pressure, and without doing any violence to the relativity postulate for the structure. But, on the illustrative analogy of a rotational æther, it had been familiar that, for any static model, all that was required was to bring into play in the theory just this hydrostatic pressure that obviously can subsist in such an æther. Yet, viewed from this more concrete or physical point of view, that was not sufficient; for it was immediately recognisable that such a shell model is an unstable structure, much as is actually an electrified soap-bubble, thus requiring that analogies along that line had to remain in abeyance pending possible formulation of plausible slight constraints such as might protect the illustrative structure from destruction. But without assuming any definite internal structure for the electron at all—all such models are suggestive and valuable for consolidation of knowledge, none can be complete or final—we can postulate merely that it is permanent and is mobile, and explore, by mixed observation and theory, the nature of the field around it with continually increasing precision, and also the mutual influences of neighbouring electrons which arise from the superposition of their fields. This tentative procedure runs parallel to the course of actual progress: while any postulate of reduction of physical science to a self-contained

[1] An alternative form of the postulate, that nothing may be the subject of reasoning that cannot be observed, seems to imply a sense of humour.

geometric analysis in space-time may savour of reproducing the infinite with finite appliances.

It was already implicit in the Maxwellian æther-theory of half a century ago that a loss of energy δE from a material system, if it occurs by radiation, involves proportionate loss of inertial mass, of amount $\delta E/c^2$, where c is the speed of radiation: and vice versa. Such loss would have to fall on the internal relative potential and kinetic energies of the constituents of the radiating atom. There appears to be some astronomical knowledge now available, following on the lines of an idea recently introduced and explored by Dr Jeans (Monthly Notices R.A.S., November 1924, just now to hand), to estimate extreme superior limits restricting the amount and duration of radiation from the sun or a star that could be conceivable from this source of supply This new type of limit, doubtless, however, quite unapproachable, and uncertain as depending on an estimate of the internal mutual energies of the atom that may be available for running away into radiation, would stand in contrast, for example, with the famous historical estimate, enormously smaller, afforded by the running down into radiation of energy located outside the atoms, that of the mutual gravitation of the parts of the system in bulk; which was put forward in the early days of the conservation of energy by Kelvin and independently in more searching and complete manner by Helmholtz to explain the solar heat, but is now regarded on cogent grounds as inadequate for the facts of cosmic evolution when taken by itself.

Data are perhaps not entirely wanting for an estimate of the kind here described, along two ways of approach The total energy of relative positions and motions of electrons and other ultimate nuclei in the atom, such as might by the hypothesis possibly escape into energy of radiation, can on the lines of present general ideas of atomic structure be roughly set out. Indeed, the maximum possible transfer into radiant energy for all time would be measured by the total mutual energy of the initially disgregated elements, electrons and nuclei, that first fall into chemical atoms, of orbital type, and then ultimately on their destruction lapse together into closest contact. It is conceded that if atomic nuclei are regarded as finite electric charges concentrated almost into mere points, thus involving practically infinite space-density and so allowing the charges to approach infinitely near, this amount of possible radiation could tend to increase beyond measure. But that would introduce infinities in all directions, for example, infinite inertia of an atom, and is perhaps not contemplated on any kind of theory. (As the complete transformation, vice versa, of the gases from 1 c.c. of radium releases heat to the order of 10^7 calories, an easy computation shows that the preponderant nuclear energies of the atoms must there be very deeply drawn upon, as, of course, is now familiar, though not so much as to involve recognisable diminution of mass Cf. Rutherford and his coadjutors, as reported in his treatise.)

There seems to be another corroborating mode of approach, which must indeed be obvious; one which also affords some confirmation of our postulate of indestructibility of the primordial atoms. It lies in the cardinal discovery of Aston that the standard relative atomic masses of all the chemical elements are expressible in high approximation by integers, with only one challenging exception. When in the cosmic process two atoms are imagined to combine, forming an atom of a more complex kind of matter, there would thus be no room for much conversion of mass into energy: the mutual energy, residing in the local fields, that can become free to run away into radiation, must correspond to the equivalent of a very small portion, perhaps on the experimental results not more than one-tenth per cent, of the total mass, however intimate be the consolidation that is required into one central nucleus for the new atom

For astronomical purposes Dr Jeans has made an estimate of the course of evolution for the universe, if all the matter in it were classed as a form of energy convertible into radiation. He finds, on Eddington's hypotheses, that durations of the present cosmic order ranging around two hundred millions of millions of years would become conceivable Perhaps if only the mutual positional and motional energies of the ultimate discrete constituents of atoms could at the very most run into radiation, the energy thus assumed to be available (which is no measure of the duration of the system) must be reduced on the first estimate above by a factor which might be as small as 10^{-8} or as great as 10^{-5}, and on the other by a factor which could not exceed 10^{-3}

Apart from such interesting change in formulation of an ultimate cosmic problem, the object of the present discussion is to concentrate on one fundamental question, which has become conspicuous in much recent ultra-physical speculation. Is matter to be regarded as consisting irrevocably of primordial atomic structures absolutely permanent: or alternatively, discarding all structural analogies based on classical dynamical principles, are the atoms, if such then really are retained, to be considered as mere concretions or aggregations liable to dissipate entirely into energy of radiation and so vanish?

Biographical Byways.[1]

By Sir ARTHUR SCHUSTER, F.R.S.

7. OSBORNE REYNOLDS (1842–1912).

WHENEVER I hear of a man who is described as being lovable, the figure of Osborne Reynolds rises up before me; and yet I doubt whether on a casual acquaintance or in official intercourse that adjective would have suggested itself. In ordinary conversation he often took a cynical view of things; he was obstinate in adhering to his own opinion, absolutely uncompromising, and sometimes a little hasty in imputing selfish motives to his opponents. But the discordant elements of his character were fused together by an almost primitive simplicity of mind, and after closer acquaintance few could resist the charm of his strong personality.

His loyalty to friends and colleagues knew no bounds.

[1] Continued from p. 199.

In 1883, Mr. E. J. Stone, formerly Astronomer Royal at the Cape of Good Hope and—at the time—president of the Royal Astronomical Society, made a series of communications to the Society in which he claimed to show that the discrepancies between the lunar tables and the observed position of the moon had no reality, but were only natural consequences of the changes which had, from time to time, been introduced in the adopted mean solar day, and in particular, that the errors of Hansen's tables of the moon were due to the adoption of Leverrier's solar tables by the British Nautical Almanac. The matter was of the highest importance, as it affected our fundamental unit of time. The subject is intricate and full of pitfalls, but clear-headed men like Adams, Cayley, and Newcomb all came to the conclusion that Stone's assertion could not be maintained. I must have mentioned the matter to Osborne Reynolds. He had no special interest in astronomy; in fact, he knew very little about it, but he had been a fellow of Queen's College, Cambridge. So had Stone, and that was sufficient reason why Stone should be right. When I quoted Cayley and Adams it made no impression. Reynolds maintained the general thesis that when a man of established reputation has the whole scientific world against him, it is quite certain that the man who stands alone is right. After considering the subject for a few days he came to me and said: "I have gone into the question, and I remain convinced that Stone is right." Again two days later he expressed the same opinion. Another week passed and he recanted, admitting that Stone was wrong. But he had spent more than a week on a new, and probably uncongenial, subject in the forlorn hope of being able to support a friend.

An interesting chapter in the history of science could be written on the hampering effect of knowledge that is either deficient or too complete. Ignorance may lead astray, but perfect knowledge often acts as a brake and stops the car when a reckless spurt would take the driver into new territory. For the moment I am thinking of the early history of the radiometer, though this is not perhaps the best example that could be chosen. The manner in which Crookes was led from certain irregularities of weighing to the construction of his interesting little instrument was wholly admirable, and some of the steps in the research, such as the improvement of air-pumps, marked considerable advances, while other incidental results are of permanent value. But it is permissible to ask whether any one wholly conversant with the property of gases at low pressures, and therefore able to anticipate the effect discovered by Crookes, would have taken all the trouble to spend two years in demonstrating it. Even if familiar with Maxwell's radiation pressure, perfect knowledge would have recognised that there was no immediate hope of verifying it experimentally until the methods of obtaining high vacua were improved to a degree not dreamt of in those days.

There can be no doubt that the driving power of Crookes's work was the hope of discovering a new property of radiation. The first communication read before the Royal Society in December 1873 concludes with the following statement: "In the radiant molecular energy of cosmical masses may at last be found that 'agent acting constantly according to certain laws,' which Newton held to be the cause of gravity." He modified his views later, and ascribed the effect to light "even where there is no heat" (NATURE, Vol. 12, p. 124).

Reynolds recognised that the apparent repulsion could be explained without the help of unknown forces in the belief, at first, that they were due to condensed moisture evaporating under the influence of thermal radiation; but he soon replaced this view by the now generally accepted theory. Johnstone Stoney had put forward similar ideas which, nevertheless, differed in essential points.

During the winter of 1873–74 I suggested to Reynolds, as I had done to others, that the main question whether the repulsion was caused by internal or external forces could be solved in a very simple manner, by the reaction on the containing vessel. When I returned in November 1875 from the Siamese eclipse, I found controversies still raging, but no one had taken the trouble to try the crucial experiment. I was reluctant to do so myself, as a number of persons were working on the subject, and I have perhaps an exaggerated objection to cutting into what I consider to be other people's work. I repeatedly spoke to Reynolds about it in the hope that he would take the matter up. One evening after lecturing hours, while I was working alone in the Physical Laboratory, Osborne Reynolds entered the room and said: "I want you to do that experiment you spoke of, and to do it now. I have got everything ready for you." I went with him to the lecture room. We suspended the radiometer with an attached mirror, and, at the first trial, it behaved as it should. The vessel swung round as soon as the light fell on the blackened surfaces, and returned to its position of rest when the rotation of the vanes had reached the steady state. Reynolds would not listen to the proposal of a joint communication, and my paper appeared in due course in the Philosophical Transactions.

In his writings, as in his speech, Reynolds was difficult to understand. His brain seemed to work along lines different from those of the majority of us. He looked upon all things in an original manner, and the education of his children was one of them. I once found him playing with his little son, and nothing seemed to give him greater pleasure than when the boy did the opposite thing to that which he was asked to do. "Come here," said Reynolds, and when the child went further away Reynolds was delighted, interpreting the act as showing independence of spirit. The incident made a great impression on me.

In his later years Reynolds had difficulty in finding the right word, using sometimes one that had the opposite meaning to that required. This failing ultimately developed into a regular aphasia.

The value of his scientific work is admirably described in the obituary notice published by the Royal Society. It may be added that though his theory of the construction of the universe, on which he concentrated his whole strength at the end of his scientific life, received little support, it may yet find its place in reconciling the old and new physics.

In his lectures Reynolds was often carried away by his subject and got into difficulties. Some humorous incidents are related with regard to the manner in which he got out of them. He was once explaining the slide

rule to his class; holding one in his hand, he expounded in detail the steps necessary to perform a multiplication. "We take as a simple example three times four," he said, and after appropriate explanations he continued, "Now we arrive at the result; three times four is 11·8." The class smiled. "That is near enough for our purpose," said Reynolds It may be imagined that the average student was often puzzled; but nevertheless, the number of scientific engineers of high standing that he trained is a testimony to his teaching power, when he had the right material with which to deal. That power was not one of imparting knowledge but rather of stimulating thought.

Not long ago a representative of the University of Manchester lectured in the United States. At the conclusion of the lecture a gentleman stepped out from the audience, and addressing the lecturer, said: "I understand that you come from Manchester. I owe all my success in life to Osborne Reynolds, and I ask you to accept a cheque for the benefit of the University as a sign of gratitude" No one could wish for a higher testimonial than that

The Fossil Anthropoid Ape from Taungs.

By Sir ARTHUR KEITH, F.R.S

THE discovery of fossil remains of a "man ape" in South Africa raises many points of great interest for those who are studying the evolution of man and of man-like apes No doubt when Prof. Dart publishes his full monograph of his discovery, he will settle many points which are now left open, but from the facts he has given us, and particularly from the accurate drawing of the endocranial cast and skull in profile, it is even now possible for an onlooker to assess the importance of his discovery I found it easy to enlarge the profile drawing just mentioned to natural size and to compare it with corresponding drawings of the skulls of children and of young apes. When this is done, the peculiarities of Australopithecus become very manifest

Prof Dart regrets he has not access to literature which gives the data for gauging the age of young anthropoids In the specimen he has discovered and described, the first permanent molar teeth are coming into use Data which I collected 25 years ago show that these teeth reach this stage near the end of the 4th year, two years earlier than is the rule in man and two years later than is the rule in the higher monkeys In evolution towards a human form there is a tendency to prolong the periods of growth Man and the gorilla have approximately the same size of brain at birth, the rapid growth of man's brain continues to the end of the 4th year; in the gorilla rapid growth ceases soon after birth

Prof Dart recognises the many points of similarity which link Australopithecus to the great anthropoid apes—particularly to the chimpanzee and gorilla. Those who are familiar with the facial characters of the immature gorilla and of the chimpanzee will recognise a blend of the two in the face of Australopithecus, and yet in certain points it differs from both, particularly in the small size of its jaws.

In size of brain this new form is not human but anthropoid In the 4th year a child has reached 81 per cent. of the total size of its brain; at the same period a young gorilla has obtained 85 per cent. of its full size, a chimpanzee 87 per cent. From Prof Dart's accurate diagrams one estimates the brain length to have been 118 mm.—a dimension common in the brains of adult and also juvenile gorillas The height of the brain above the ear-holes also corresponds in both Australopithecus and the gorilla—about 70 mm. But in width, as Prof. Dart has noted, the gorilla greatly exceeds the new anthropoid; in the gorilla the width of brain is usually about 100 mm., in Australopithecus the width is estimated at 84 mm. The average volume of the interior of gorillas' skulls (males and females) is 470 c.c., but occasional individuals run up to 620 c.c. One may safely infer that the volume of the brain in the juvenile Australopithecus described by Prof. Dart must be less than 450 c.c., and if we allow a 15 per cent. increase for the remaining stages of growth, the size of the adult brain will not exceed 520 c.c. At the utmost the volume of brain in this new anthropoid falls short of the gorilla maximum. Even if it be admitted, however, that Australopithecus is an anthropoid ape, it is a very remarkable one. It is a true long-headed or dolichocephalic anthropoid—the first so far known. In all living anthropoids the width of the brain is 82 per cent. or more of its length, they are round-brained or brachycephalic, but in Australopithecus the width is only 71 per cent. of the length. Here, then, we find amongst anthropoid apes, as among human races, a tendency to roundness of brain in some and to length in others. On this remarkable quality of Australopithecus Prof. Dart has laid due emphasis

This side-to-side compression of the head taken in conjunction with the small size of jaws throw a side light on the essential features of Australopithecus. The jaws are considerably smaller than those of a chimpanzee of a corresponding age, and much smaller than those of a young gorilla There is a tendency to preserve infantile characters, a tendency which has had much to do with the shaping of man from an anthropoid stage The relatively high vault of the skull of Australopithecus and its narrow base may also be interpreted as infantile characters. It is not clearly enough recognised that the anthropoid and human skulls undergo remarkable growth changes leading to a great widening of the base and a lowering or flattening of the roof of the skull. In Australopithecus there is a tendency to preserve the fœtal form.

When Prof Dart produces his evidence in full he may convert those who, like myself, doubt the advisability of creating a new family for the reception of this new form. It may be that Australopithecus does turn out to be "intermediate between living anthropoids and man," but on the evidence now produced one is inclined to place Australopithecus in the same group or sub-family as the chimpanzee and gorilla. It is an allied genus. It seems to be near akin to both, differing from them in shape of head and brain and in a tendency to the retention of infantile characters. The geological evidence will help to settle its relation-

ships. One must suppose we are dealing with fossil remains which have become embedded in the stalagmite of a filled-up cave or fissure of the limestone cliff.

May I, in conclusion, thank Prof. Dart for his full and clear description, and particularly for his accurate drawings. One wishes that discoverers of such precious relics would follow his example, and, in place of reproducing crude tracings and photographs, give the same kind of drawings as an engineer or an architect prepares when describing a new engine or a new building

By Prof G. ELLIOT SMITH, F R S

IT is a great tribute to Prof. Dart's energy and insight to have discovered the only fossilised anthropoid ape so far obtained from Africa, excepting only the jaw of the diminutive Oligocene Propliopithecus from the Egyptian Fayum. Whether or not the interpretation of the wider significance he has claimed for the fossil should be corroborated in the light of further information and investigation, the fact remains that his discovery is of peculiar interest and importance.

The simian infant discovered by him is an unmistakable anthropoid ape that seems to be much on the same grade of development as the gorilla and the chimpanzee without being identical with either. So far Prof Dart does not seem to have "developed" the specimen far enough to expose the crowns of the teeth and so obtain the kind of evidence which in the past has provided most of our information for the identification of the extinct anthropoids Until this has been done and critical comparisons have been made with the remains of Dryopithecus and Sivapithecus, the two extinct anthropoids that approach nearest to the line of man's ancestry, it would be rash to push the claim in support of the South African anthropoid's nearer kinship with man Prof. Dart is probably justified in creating a new species and even a new genus for his interesting fossil: for if such wide divergences between the newly discovered anthropoid and the living African anthropoids are recognisable in an infant, probably not more than four years of age, the differences in the adults would surely be of a magnitude to warrant the institution of a generic distinction.

Many of the features cited by Prof Dart as evidence of human affinities, especially the features of the jaw and teeth mentioned by him, are not unknown in the young of the giant anthropoids and even in the adult gibbon.

The most interesting, and perhaps significant, distinctive features are presented by the natural endocranial cast They may possibly justify the claim that Australopithecus has really advanced a stage further in the direction of the human status than any other ape. But until Prof. Dart provides us with fuller information and full-size photographs revealing the details of the object, one is not justified in drawing any final conclusions as to the significance of the evidence.

The size of the brain affords very definite evidence that the fossil is an anthropoid on much the same plane as the gorilla and the chimpanzee. But while its brain is not so large as the big gorilla-cast used for comparison by Prof. Dart, it is obvious that it is bigger than a chimpanzee's brain and probably well above the average for the gorilla. But the fossil is an imperfectly developed child, whose brain would probably have increased in volume to the extent of a fifth had it attained the adult status. Hence it is probable the brain would have exceeded in bulk the biggest recorded cranial capacity for an anthropoid ape, about 650 c c. As the most ancient and primitive human brain case, that of Pithecanthropus, is at least 900 c c. in capacity, one might regard even a small advance on 650 c.c. as a definite approach to the human status The most suggestive feature (in Prof Dart's Fig. 5, p 197) is the position of the sulcus lunatus and the extent of the parietal expansion that has pushed asunder the lunate and parallel sulci—a very characteristic human feature.

When fuller information regarding the brain is forthcoming—and no one is more competent than Prof Dart to observe the evidence and interpret it—I for one shall be quite prepared to admit that an ape has been found the brain of which points the way to the emergence of the distinctive brain and mind of mankind Africa will then have purveyed one more surprise—but only a real surprise to those who do not know their Charles Darwin But what above all we want Prof Dart to tell us is the geological evidence of age, the exact conditions under which the fossil was found, and the exact form of the teeth.

By Sir ARTHUR SMITH WOODWARD, F.R S

THE new fossil from Taungs is of special interest as being the first-discovered skull of an extinct anthropoid ape, and Prof Dart is to be congratulated on his lucid and suggestive preliminary description of the specimen As usual, however, there are serious defects in the material for discussion, and before the published first impressions can be confirmed, more examples of the same skull are needed

First, as Prof. Dart remarks, the fossil belongs to an immature individual with the milk-dentition, and, so far as can be judged from the photograph, I see nothing in the orbits, nasal bones, and canine teeth definitely nearer to the human condition than the corresponding parts of the skull of a modern young chimpanzee The face seems to be relatively short, but the lower jaw of the Miocene Dryopithecus has already shown that this must have been one of the characters of the ancestral apes The symphysis of the lower jaw may owe its shape and the absence of the "simian shelf" merely to immaturity; but it may be noted that a nearly similar symphysis has been described in an adult Dryopithecus, of which it may also be said that "the anterior symphyseal surface is scarcely less vertical than that of Heidelberg man" (see diagrams in Quart. Journ. Geol Soc., vol 70, 1914, pp 317, 319)

Secondly, the Taungs skull lacks the bones of the brain-case, so that the amount and direction of distortion of the specimen cannot be determined. I should therefore hesitate to attach much importance to rounding or flattening of any part of the brain-cast, and would even doubt whether the relative dimensions of the cast of the cerebellum can be relied on. Confirmatory evidence is needed of the reality of appearances in such a fossil.

In the absence of knowledge of the skulls of the fossil anthropoid apes represented by teeth and fragmentary jaws in the Tertiary formations of India, it is premature to express any opinion as to whether the direct

ancestors of man are to be sought in Asia or in Africa. The new fossil from South Africa certainly has little bearing on the question.

Palæontologists will await with interest Prof. Dart's detailed account of the new anthropoid, but cannot fail to regret that he has chosen for it so barbarous (Latin-Greek) a name as Australopithecus.

By Dr W. L. H. DUCKWORTH.

PROF. DART'S description of the fossil skull found at Taungs in Bechuanaland shows that this specimen possesses exceptional interest and importance. Should the claims made on its behalf prove good, then its discovery will in effect be comparable to those of the Pithecanthropus remains, of the Mauer mandible and the Piltdown fragments. In the following paragraphs I venture to make some comments based upon perusal of the article published in NATURE of February 7.

First of all, the fact that the fragments came immediately under notice of so competent an anatomist as Prof. Dart establishes confidence in the thoroughness of the scrutiny to which they have been subjected That the history of the specimen should be known precisely from the time of its release from the limestone matrix, provides another cause for satisfaction.

The specimen itself at once raises a number of questions, and, as Prof Dart evidently realises, these fall into at least two categories. The first question arising out of the discovery is the status of the individual represented by these remains. But the answer to that question, and the presence of such a creature in South Africa, affect other problems. The latter include inquiry into the probable locality of origin of the simian and human types, and the search for evidence of dispersion from a centre, or along a line of successive migrations

In dealing with the first problem, Prof. Dart has surveyed a considerable number of structural details, and he concludes that the specimen represents an extinct race of apes intermediate between living anthropoid apes and mankind. The specimen comprises the greater part of a skull with the lower jaw still in place (or nearly so) The number and characters of the teeth testify to the immaturity of the individual. The evidence on the last-mentioned point is quite definite, and interest thus comes to be centred in the status assigned to the specimen, namely, that of a form intermediate between the living anthropoid apes and man himself.

Prof Dart places the specimen on the side of the living anthropoid apes in relation to the interval separating these from man At the same time, it is claimed that this new form of ape is more man-like than any of the existing varieties of anthropoid apes; and so it comes about that the decision turns on the claims made for the superiority of the new ape to these other forms.

The report shows that (as noted above) many structural details have been scrutinised, and that all accessible parts of the specimen have been examined. The observations relate not only to the external parts of the skull and lower jaw, but also to the endocranial parts exposed to view by the partial shattering of the brain-case. The claims advanced on behalf of the higher status of the specimen are based, therefore, upon a number and variety of such details. Should Prof. Dart succeed in justifying these claims, the status he proposes for the new ape-form should be conceded. Much will depend on the interpretation of the features exhibited by the surface of the brain, as also upon that of all the characters connected therewith, and since Prof. Dart is so well equipped for that aspect of the inquiry, his conclusions must needs carry special weight there. In regard to the brain and its characters, I find the tracing of the contour of an endocranial cast in a gorilla-skull shown in Fig. 6 rather surprisingly flattened, and almost suggestive of the influence of age.

Among the anatomical characters enumerated in the article, some appear to me to possess a higher value in evidence than others. As good points in favour of the claims, there may be cited, in addition to the cerebral features to which reference has just been made, the level of the lower border of the nasal bones in relation to the lower orbital margins, the (small) length of the nasal bones, the lack of brow-ridges (even though the first permanent tooth has appeared fully), the steeply-rising forehead, and the relatively short canine teeth

On the other hand, I feel fairly certain that some of the other characters mentioned are related preponderantly to the youthfulness of the specimen. Fully to appreciate the latter, demands not only the handling of it, but also thorough survey of a collection of immature (anthropoid ape) crania. The development of the "shelf" at the back of the symphysis of the lower jaw may almost certainly be delayed in some individuals (gorillas) Even the level of the lower border of the nasal bones is subject to some variation, and in young gorillas before the first permanent tooth has emerged fully, that level may be (as in man) above the level of the orbital margin. Generally, the elimination and detachment of features influenced largely by the factor of age demand special attention.

If, however, the good points can be justified, then these characters of youth will not gravely affect the final decision.

However these discussions may end, the record remains of the occurrence of an anthropoid ape some two thousand miles to the south of the nearest region providing a record of their presence. So far as the illustrations allow one to judge, the new form resembles the gorilla rather than the chimpanzee, that is, an African, not an Asiatic form of anthropoid ape. In this respect the new ape does not introduce an obviously disturbing factor. Disturbance, and the re-casting of disturbed views, might nevertheless be caused in two other directions. Thus, the determination of the geological antiquity of the embedding of the fossil remains might have such an effect, were the estimate such as to carry that event very far back in time. Again, a comparison of the new ape with the fossil forms from India (Siwaliks) remains to be made, and it may be productive of results bearing on the relation of the African and the Asiatic groups. In any case, opinion must needs conform to the situation created by this discovery.

If in these notes there have been passed over those observations and reflections wherewith Prof. Dart has illustrated and supported his views, such omissions are not due to want of appreciation, but to lack of capacity and space for their adequate treatment.

Obituary.

MR. OLIVER HEAVISIDE, F.R.S.

BY the death of Oliver Heaviside the scientific world loses one of its most original thinkers. He was born in London on May 13, 1850, and his uncle was Sir Charles Wheatstone, the practical founder of modern telegraphy. The Heaviside family were interested in music and telegraphy His brother Charles, who lived at Torquay, was connected with the musical industry, and his brother, Arthur West Heaviside, was a superintending engineer to the Post Office and one of the pioneers of radio telegraphy.

After leaving school Heaviside obtained a post with the Great Northern Telegraph Co. at Newcastle-on-Tyne, which he held for several years. During this period he communicated papers to the *English Mechanic*, the *Telegraphic Journal* and the *Philosophical Magazine* These papers are of more than average ability and show great promise For example, in 1873 he showed that quadruplex telegraphy was a possibility. Unfortunately, in 1874, increasing deafness made him retire from business life and he went to live in Devon. He now devoted himself whole-heartedly to the study of electricity and its applications. He published many papers which gradually became more and more technical and more and more difficult to understand, as it became necessary, in order to avoid repetition, to assume that the reader knew some of the writer's previous work. Consequently he had difficulty in getting them published in the ordinary technical journals. At that period there were few referees competent to understand them. As a rule they suggested that the paper should be cut down. The result was that many necessary mathematical links were left out, and the expert has no easy task to follow the reasoning. Fortunately, several well-known scientific men—in particular Sir Oliver Lodge, Prof. Perry, and Dr. G. F. C. Searle—had noted the advent of a mathematical physicist of superior ability and helped him to get his papers published. He had, however, to run the gauntlet of a good deal of unintelligent criticism, and none of his discoveries received that immediate recognition which their merit deserved.

Heaviside communicated to the Society of Telegraph Engineers (now the Institution of Electrical Engineers) a paper solving the problem of the electrostatic and electromagnetic interference between overhead parallel wires, a problem which has come to the front at the present time. His methods of measuring mutual inductance published in 1887 are of great value in themselves, and, like most of Heaviside's work, have been most fruitful in suggesting extensions to others. He was the first to solve the problem of the high-frequency resistance and inductance of a concentric main. It would probably have remained neglected for many years had not Kelvin given some of his results in his presidential address to the Institution of Electrical Engineers in 1889.

From the practical point of view, Heaviside's most important work was laying the foundation of the modern theory of telephonic transmission; a theory which has proved a veritable gold mine for the practical telephonist. He pointed out that the difficulties which arose in telephony were due to the different attenuations and different velocities of the various component waves which carry the necessary currents His theory of the distortionless circuit showed clearly the lines on which telephony could be developed Working on these lines some ten years later, Prof Michael Pupin in the United States developed his loading coils, and long-distance telephony was born.

In 1891 Heaviside was elected a fellow of the Royal Society In 1892 his earlier "Electrical Papers" were published in two volumes The value of his work began then to be realised by electricians He did perhaps more than any man to show the value of a knowledge of physics and of mathematical theory in the electrical industry. Pupin has said that Heaviside did much "to introduce the living language of physics in place of the sign language of mathematical analysis" Heaviside's pioneering work will always take a leading place in the history of electrical theory

The first volume of Heaviside's great work on "Electromagnetic Theory" was published in 1893 and the second volume in 1899 His original intention was to publish the third volume in 1904 and the concluding volume in 1910, but this he found impossible, and so published the third and concluding volume in 1912.

Heaviside was the first to give the theory of the steady rectilinear motion of an electron through the ether, a theory which has been developed by others—notably by Searle—with important results By an electron he simply meant an electric charge He pointed out many years ago that even if we knew the constitution of the electron we would be a long way from finality There is no absolute scale of size in the universe As it is boundless in one way towards the great, it is equally boundless towards the small He was one of the first to predict the increase of mass of a moving charge when its speed becomes very great To verify all Heaviside's reasoning and especially to examine the validity of some of his mathematical methods will provide work for many mathematicians and physicists. He strongly resented the contemptuous tone adopted by some mathematicians when referring to his work on divergent and semi-convergent series. He had found them useful in general theory and for computing purposes, and so he naturally considered his critics prejudiced. In June 1902 he wrote the article on the "Theory of the Electric Telegraph" in the "Encyclopædia Britannica." Many theorems given in this article are constantly quoted by the writers of text-books. In particular his description of what is now called the Heaviside layer, by means of which Hertzian waves are supposed to be bent round the earth, is familiar to every radio engineer

In the later years of his life Heaviside was one whom every electrical engineer delighted to honour In 1908 he was elected an honorary member of the Institution of Electrical Engineers. When in 1921 the Faraday Medal was founded, it was universally considered most appropriate that Heaviside should be the first Faraday medallist. The president, Mr. J. S. Highfield, went to Torquay and presented it to him in person He was an honorary Ph.D. of Göttingen, an honorary member of the Literary and Philosophical Society of Manchester and of the American Academy of Arts and Sciences.

For fifty years Heaviside lived practically a hermit's life at Torquay. He was a good correspondent, but very difficult to approach personally In his later years Dr. and Mrs. Searle of Cambridge were practically his only friends The Government gave him a civil list pension, and about twenty years ago Mr Asquith increased it The Institution of Electrical Engineers took a filial interest in him, and it is gratifying to remember that during the last few years of his life the Institution kept in constant touch with him. In the preface to his "Electrical Papers" he says that the question "Will it pay?" never interested him He was, he said, mainly actuated by philanthropic motives Looking back—as he has probably saved the Government of every large civilised country in the world millions of pounds in the costs of their telephone schemes—he was truly a philanthropist He died at Torquay on Tuesday, February 3, and was buried on Friday, February 6, in the same grave as his father and mother, only relatives and Mr R H. Tree, representing the Institution of Electrical Engineers, being present Thus ended the life of one who has left a record of work which has proved of great value to the world.

A. RUSSELL.

PROF N. KULCHITSKY.

THE death of Prof Nicholas Kulchitsky on January 30, at the age of sixty-nine, has removed one of the foremost of Russian histologists. For many years he occupied the chair of histology at the University of Charkov, where he accomplished most of his researches His methods of fixing and staining tissues are now in universal use—those for smooth muscle are particularly well known. He devoted much attention and made numerous important observations on the distribution of connective tissue in the intestinal tract and other organs His text-books of histology are standard works and at present are commonly used by Russian medical students. That his work was well known outside his own country is shown by the fact that he was an honorary member of the Anatomical Society of Great Britain and Ireland.

Prof. Kulchitsky was a man of wide interests and sympathies. He responded whole-heartedly to the request of his government for his expert assistance in the work of the Ministry of Education, and for a number of years he held the post of administrator of education in the Charkov district and later in the Petrograd district During the period just before the first revolution he held the post of Minister of Education During the period of upheaval he suffered severely from the hardships attending revolution and counter-revolution. In order to maintain his family and himself he was reduced to hard manual labour. That he was able to live through these hardships, at his advanced age, is evidence of his characteristic power for hard work and perseverance At length he was fortunate enough to embark on a British refugee ship together with remnants of Wrangel's forces, and this brought him to London, where he found shelter and opportunities for continuing his scientific endeavours.

During the brief time of less than three years, as lecturer in the Department of Histology at University College, London, Kulchitsky was largely concerned with the teaching of students, but he also completed several important and significant researches. Not the least of these is that in which he showed that voluntary muscles are supplied by both medullated and sympathetic nerve fibres, the former being attached to the large muscle fibres, whilst the latter supply small muscle fibres These facts led to the physiological and clinical investigations of the late Prof. Hunter, who showed that the smaller fibres are responsible for the maintenance of tone in voluntary muscles. The work has found important applications in the operation of dividing the sympathetic nerves supplying the muscles affected in cases of spastic paraplegia

Prof Kulchitsky and Prof. J. I. Hunter were associated in their work, and it is indeed a sad coincidence that the untimely death of young Prof. Hunter should so soon have been followed by the unfortunate accident, a fall down an elevator shaft at University College, which led to the death of Prof. Kulchitsky

The loss of Prof. Kulchitsky is deeply mourned by all his associates and friends at University College and by the scientific world in general G. V A.

DR. DAVID B. SPOONER

THE Archæological Department of the Indian Government has suffered a heavy loss by the death at Agra on January 30 of Dr. David B. Spooner, who had been Deputy Director-General of Archæology in India since 1919 and had acted on one occasion as head of the Survey during Sir John Marshall's absence on leave. Dr. Spooner's connexion with the Department commenced at the opening of the present century, and there can be no doubt that by his own efforts and achievements he did much towards giving practical effect to the policy of conservation and research inaugurated by Lord Curzon in 1902 Up to that date, official efforts to preserve the monuments of past ages and to investigate the hidden remains of antiquity were "spasmodic, desultory, unscientific and planned on a penurious scale" With the appointment of a Director-General of Archæology and a staff of able assistants, among whom Dr. Spooner was deservedly considered one of the most capable, there began that enormous development of historical and archæological study which has been one of the most striking features of the twentieth century in India.

Dr. Spooner did excellent work as Superintendent of the difficult Frontier Circle; but his name is more likely to be remembered in connexion with his excavations at Pataliputra, now known as Patna, the ancient capital of the Maurya dynasty of Magadha, and with the somewhat startling theory which he advanced as to the origin of the family of Chandragupta and his successors The fact that the palace of the Mauryas, discovered near the modern village of Kumrahar, was almost certainly designed in imitation of the Persian palace at Persepolis, together with other traces of Iranian influence upon the practice of the Mauryan court, led Dr. Spooner to assert that Chandragupta and his successors were of Persian origin. This theory, which he published in the Journal of the Royal Asiatic Society, has been accepted by no one except, possibly, certain Parsi scholars, who were naturally gratified at the idea of a "Zoroastrian period" of Indian history. But while no one disputes the fact that Persian institu-

tions were familiar to the people of northern India in the fourth and third centuries B.C., the assumption of an Iranian origin for the rulers of Magadha has no historical warranty at present, and involves the rejection of important traditional and literary evidence as to their descent

Dr. Spooner's research work at Kumrahar needs no commendation, and he was probably led into his novel speculations about the Mauryas by his intense enthusiasm—the very quality which, combined with sedulous activity, rendered him so valuable a servant of the Government of India *Ave atque vale.* S. M. E

WE regret to announce the following deaths:

Sir Anderson Critchett, Bart., K.C.V.O., surgeon-oculist to the King, first president of the Council of British Ophthalmologists, president in 1894 and 1899 of the Ophthalmological Society of the United Kingdom and in 1913 of the Ophthalmic Section of the International Medical Congress held in London, on February 9, aged seventy-nine

Dr. Horace T. Brown, F.R.S., distinguished for his work on the chemistry of carbohydrates, on the assimilation of atmospheric carbon dioxide by leaves, and on gaseous diffusion through small apertures, on February 6, aged seventy-six.

Current Topics and Events.

WIDESPREAD interest has been aroused among the general public by the publication of Prof. Dart's account of the discovery of *Australopithecus africanus*, or the Taungs Man, as the Press has elected to call him, in last week's issue of NATURE. Although the discovery dated from November last, the news had been carefully guarded, and it was only when a cable was received in England on February 4, and appeared in the Press on the following day, on the eve of the publication of the article in NATURE, that it became known. Notwithstanding the absence of precise details, the importance of the news was at once recognised by the leading London and provincial daily papers, which quoted freely from Prof. Dart's article as soon as it was available. In another part of this issue, Sir Arthur Keith, Prof. G. Elliot Smith and Dr. W. L. H. Duckworth discuss the significance of the discovery.

THE debt which the modern civilised world owes to science has seldom been acknowledged so generously, or expressed so eloquently, by responsible statesmen as by President Coolidge and by Mr. C. E. Hughes, Secretary of State, in their addresses to the recent meeting of the American Association for the Advancement of Science at Washington, D.C., which have been printed in a recent issue of *Science*. No other single agency, says the President of the United States, has relied so much upon the work of men and women of science as has his government, which has been foremost in employing and most liberal in endowing science, although it cannot claim to have been "impressively liberal" to the scientific workers whom it has employed. The scientific work done under the administrative departments has, he says, been of enormous value to the whole people. Men of science are "the wonder-workers of all the ages", the discoveries made by them have become commonplaces because their number has paralysed the capacity of the mind for wonderment. Representatives of social and political organisations regard the march of science with awe, and sometimes with fear, when they ask themselves what will be the next revolution to which their schemes will have to be adapted; but the conviction that science works for the public weal, and that at the worst it saves life from being very monotonous, restores their confidence. It has taken endless ages to create in men the courage that will accept the truth simply because it is the truth. Comparatively few men are sufficiently gifted to be able to use the scientific method in seeking for the truth, but they no longer fear the results to which it leads. Truth is essential, and therefore all encouragement should be given to men of science and of faith.

MR. HUGHES spoke on the value of science in promoting international co-operation and concord. Science may forge new and terrible weapons of destruction, but she is far more eloquent as she points to the wastes of strife, to the retarding of progress, and to the vast opportunities which are open to those peoples who will abandon mutual fears and destroy artificial barriers to community of enterprise. Each nation should collect, collate, and safeguard all data and records made within its territory, and should make them readily available to other nations. International co-operation in research is absolutely necessary, and both national research organisations and the International Research Council are doing good work and opening up a new era of international co-operation in science. Scientific method is needed in government, in making and administering the law. The scientific attitude of mind is needed because it comprises search for pure knowledge, distrust of phrases and catchwords, hatred of shams, willingness to discard outworn beliefs, and, above all, faith in humanity and zeal for the public good.

THE Right Hon. T. R. Ferens, High Steward of Hull, has presented to Hull the princely sum of 250,000*l.* as a nucleus towards a University College for the city. In his letter to the Lord Mayor announcing his intention of making the gift, Mr. Ferens stated that he had carefully consulted university professors and others interested in educational matters, and was satisfied that the time was arriving when Hull should join other cities, such as Birmingham, Manchester, Liverpool, Leeds, etc., in giving opportunities to its sons and daughters for higher education. We believe it was at the meeting of the British Association at Hull, when the retiring president, Sir Edward Thorpe, and the president, Sir Charles Sherrington, were the guests of Mr. Ferens, that the idea was first suggested. In addition to this magnificent gift, a new Art Gallery, costing something like 90,000*l.*, together with its site in the centre of the city, has been presented by Mr. Ferens.

He has given more than 11,000*l.* towards pictures for the permanent collection, without which the probability is the present Art Gallery in the City Hall would not have existed Other gifts of Mr Ferens include more than 9000*l.* for the site for a new technical college, amounts set aside for scholarships, playing fields; almshouses, boating-lake, and similar objects.

LONGEVITY among scientific men is exemplified in a signal manner through the ninetieth anniversary of the birth of a distinguished zoologist, the Rev. T. R R Stebbing, F.R.S , an event which occurred on February 6, and was duly celebrated at his home at Tunbridge Wells The record of the Stebbing family with the Royal Society, from father to son, is noteworthy when we recall that 1765, 1845, and 1896 are, respectively, years of family elections into that body Born in London, Mr Stebbing was the fourth son of the Rev Dr. Stebbing, many years acting editor of the *Athenæum*, indeed almost from its foundation in 1828. Incidentally, we may remark that the third son, Mr William Stebbing, for long Delane's right-hand man on the staff of the *Times*, is also alive Mr Stebbing's life studies in zoological science have been concerned principally with the Crustacea His report upon the Amphipoda of the *Challenger* Expedition occupies three quarto volumes, comprising 1774 pages of letterpress and 212 plates It was accompanied by a bibliography giving a critical report of everything that had been written respecting these Crustacea from the time of Aristotle to the year 1887 This detailed analysis occupies more than 600 pages, being in fact a complete history of the group Mr Stebbing has always been greatly interested in promoting local scientific societies His efforts in this connexion in the south-east of England, jointly with the late Mr. George Abbott, were referred to in NATURE of February 7, p 201 Mr Stebbing was zoological secretary of the Linnean Society, 1903–1907, and Linnean medallist, 1908. We proffer our heartiest congratulations to him upon the auspicious occasion of a nonagenarian birthday

DR. J H JEANS gave the sixteenth Kelvin Lecture to the Institution of Electrical Engineers on February 6 He chose as his subject electrical forces and quanta, and gave a masterly résumé of the theories of relativity and quanta. Starting with Einstein's hypothesis he stated that the whole theory of gravitation and of electromagnetic forces can be worked out by pure geometry When, however, we come to the theory of quanta we have to determine the magnitude of the quantum, and so it is necessary to have recourse to experiment He considers that there is now no room for doubt as to the substantial accuracy of Einstein's relativity theory It provides a general dominating principle, to which all phenomena must conform It helps us to discover the laws according to which events occur, but has nothing to do with why they occur. It is unscientific to suppose an ether unless there is an absolute necessity for it The hypothesis is unnecessary, in Dr Jeans's opinion, as the explanations are entirely satisfactory without it. *A fortiori* it is hopelessly unscientific to presuppose two or more ethers. In his opinion the last twenty-five years will rank as one of the most fruitful and important periods in the history of physics. In an hour the lecturer covered a very wide field. He touched on Rutherford's, Bohr's, and Sommerfeld's theory of the atom. He pointed out that the explanation of line spectra is one of the most satisfactory in the whole range of physics, the numerical accuracy of the theory rivalling the most accurate of astronomical calculations. He is of opinion that the theory of a mechanical ether believed in by Faraday and Maxwell is dead. As soon as we pass beyond the minute range covered by the Newtonian mechanics and the classical electro-dynamics, the picture presented to us by the quantum dynamics takes us by surprise We find that Nature consists of a series of abrupt jumps These jumps are so minute and so close together that they produce the illusion of continuous motion, and no satisfactory mechanical explanation has yet been given

THE fourth annual report of the British Electrical and Allied Industries Research Association has now been published It is stated that the results obtained last year represent a real contribution to progress in the affected industries, but nothing of a spectacular character has been discovered Hitherto commercial research has been concerned mainly with the finding of the values of physical constants Little has been done in the way of obtaining new scientific knowledge It is stated that the discoveries of Sir J J. Thomson and Sir E Rutherford are opening up immense fields of knowledge which may not only revolutionise existing methods of design but even alter the nature of the activities of the whole industry. The Association is giving close attention to the possibilities of work in this direction It is considered, for example, that there is necessity for fundamental research on a large scale into the phenomena of dielectrics This of course is of great interest to the cable and therefore to the whole electrical industry We shall be very interested to note the results of these great schemes of co-operative research

THE late Mr. Thomas L. Gray, who died about a year ago, bequeathed the residue of his estate, which is expected to amount to about 7000*l.*, to the Royal Society of Arts for the purpose of founding a memorial to his father, Thomas Gray, formerly head of the Marine Department of the Board of Trade. According to the Society's journal, the bequest is to be known as "The Thomas Gray Memorial Trust," and the income derived from it is to be devoted to "the advancement of the science of navigation and the scientific and educational interests of the British Mercantile Marine." It is suggested in the will that these objects may be achieved by offering prizes for new inventions relating to navigation, by making grants for scientific research and for lectures on the subject, and by providing scholarships for students or teachers and offering prizes for essays on and awards for the saving of life at sea. Thomas Gray

was in charge of the Marine Department during the 'seventies and 'eighties, when British shipping was developing rapidly, and took a prominent part in formulating the present system of regulation and control.

THE issue of *Die Naturwissenschaften* for January 16 is devoted to an account of the foundation on January 14, 1845, of the Physikalischen Gesellschaft of Berlin by Profs. Beetz, Brücke, Karsten, Knoblauch and Du Bois-Reymond, and its subsequent history Profs Warburg, Goldstein, Scheel, Pringsheim and Planck are responsible for an interesting and well-illustrated account of the Society and its activities The five founders are shown in the frontispiece, which in itself makes an interesting study of professorial attire Profs Clausius, Quincke, Kundt and Kohlrausch form another group, and separate portraits are given of Profs Riecke, Warburg, Brucke, Kirchhoff, Helmholtz, Halske, Weierstrass, G. Wiedemann, Kronecker, Schwalbe, Werner Siemens, Hagenbach, von Bezold, Foerster, Planck and Goldstein. As the Society developed out of the physical colloquium founded by Prof. Magnus in Berlin in 1843, it is fitting that Prof. Pringsheim's recent address to the Society on the Magnus effect, its theory as developed by Prof Prandtl and its application by Dr Flettner, should be given a prominent place and that the original figures of the Magnus paper should be reproduced.

THE final sale of the Crisp collection of microscopes takes place on Tuesday, February 17, at Stevens's Auction Rooms, where in 1920 and 1921 the other portions of the collection were sold In the catalogue which Messrs Stevens have issued, 371 lots are detailed, arranged in groups —(1) Simple microscopes and small pocket compound microscopes, (2) compound microscopes dating from the seventeenth century to the introduction of achromatism in the early part of the nineteenth century; (3) optical cabinets, solar and projection microscopes The various Nuremberg wooden microscopes form another small group. In each group, the instruments are catalogued approximately in chronological order. Illustrations are given of fourteen of the earlier and more interesting instruments, including the unique silver microscope made by G. Adams, a Hooke microscope, and original examples by Campani, Marshall, and Lindsay. The whole collection, which consisted of about 3000 microscopes, was formed during the latter half of the last century by the late Sir Frank Crisp, Bart., who became the leading authority on the history and development of the instrument. He frequently expressed his intention of presenting his collection to the Science Museum at South Kensington, so that it might become the property of the nation.

AT a meeting of the Dominions and Colonies Section of the Royal Society of Arts on January 27, Mr. W. R. Dunlop, lately professor of economics under the auspices of the Colonial Office, read a paper entitled "Economic Research in Tropical Development." Starting from the premise that the great question of economics is why some people, individually or collectively, are better off than others, Mr. Dunlop said that useful and illuminating results can be obtained in the tropical world, by contrasting one country which is undeveloped and poorly off with another that is relatively highly developed and extremely well off Taking British Guiana in South America, and British Malaya in the East, the total population and external trade of the former in 1923 were 300,000 and 6,426,607*l*, while those of the latter were 3½ millions and 147,945,860*l*. As countries go, both are similar in size (comparable to the area of the United Kingdom), both are fertile, and both have mineral and other resources The difference in extent of development is fundamentally due to (*a*) difference in world geographical position, (*b*) difference in mineral resources, (*c*) internal geographical disadvantages in the case of British Guiana On the whole, British Malaya is also more efficient industrially than British Guiana Concerning efficiency in public administration, Mr Dunlop directed attention to the fundamental importance of transport, public health, land administration, forestry and scientific research of all kinds in tropical economic development Comparison of existing policies in these matters in British Guiana and British Malaya shows striking differences In conclusion, Mr Dunlop said that he used British Guiana and British Malaya as illustrations providing data and proof for demonstrating the nature of the research he was advocating.

APPLICATIONS are invited for some junior professional assistantships at the Meteorological Office Candidates must hold an honours degree in mathematics or physics Written applications should be addressed to the Secretary (S 2), Air Ministry, Adastral House, W.C.2

THE Royal Aircraft Establishment, South Farnborough, Hants, is requiring a test assistant for aerial photographic work. Candidates should possess some knowledge of chemistry, preferably photographic chemistry, and be medically fit for flying Applications should be marked A. 46 and be sent to the Superintendent of the Establishment

SIR OTTO BEIT, Bt., F.R.S., Sir Sidney Frederic Harmer, F.R.S., Director of the Natural History Departments, British Museum, and Sir Frank Short, Royal Academician, president of the Royal Society of Painter-Etchers, have been elected members of the Athenæum under the provisions of Rule 11. of the Club, which empowers the annual election by the committee of a certain number of persons of distinguished eminence in science, literature, the arts, or for public service

SHORTLY before 10 P.M. on February 1, a slight earthquake was felt in the south-west of Cornwall, at Penzance, Camborne, Truro, etc., and the Scilly Isles. Records have also come from Brest and Jersey. The disturbed area probably contained about 17,000 square miles, and its centre apparently lay to the west of the Channel Islands. In the much stronger earthquakes of January 28, 1878, and May

30, 1889, the centre lay to the east of Jersey It has been suggested that the shock was due to the subsidence of disused mine-works, but the greatest known area disturbed by such earth-shakes is less than 150 square miles, and, owing to the small depth of the origin in such cases, the intensity is always great near the centre of the area and declines rapidly outwards

At the annual meeting of the Royal Microscopical Society held on January 21, the following were elected as officers and members of the Council for the ensuing year *President*, Mr. A. Chaston Chapman; *Vice-Presidents*, Prof F J. Cheshire, Mr M T Denne, Sir Robert A Hadfield, Bart, Dr R J Ludford, *Treasurer*, Mr C F Hill, *Honorary Secretaries*, Mr J E Barnard, Dr J A. Murray, *Members of Council*, Mr S C Akehurst, Mr E W Bowell, Rev Canon G R Bullock-Webster, Dr H. G Cannon, Dr C Da Fano, Mr E H Ellis, Prof R Ruggles Gates, Mr T H Hiscott, Mr J W Ogilvy, Mr D J Scourfield, Dr C Tierney, Mr H Wrighton, *Librarian*, Mr R. Paulson, , *Editor*, Dr J W H Eyre, *Curator of Instruments*, Mr W. E Watson Baker, *Curator of Slides*, Mr E. J Sheppard

At the last meeting of the Illuminating Engineering Society on Jan 27, a paper was read by Mr J W T Walsh, of the National Physical Laboratory, Teddington, dealing with some little-understood aspects of the effect of shadows in lighting problems It is well known that the shadows cast by indirect lighting systems—for example, when light is received by reflection from a white ceiling—are so soft as to be inappreciable to the eye In fact such systems have sometimes been described as "shadowless" Mr Walsh was able to show that what the eye cannot perceive the photometer can detect, and that in fact the obstruction of light by a person's body or adjacent machinery, etc, may in such cases cause a very marked diminution in the available illumination Similar conditions apply when one is dealing with daylight from a white sky, yielding ill-defined shadows Methods of calculating the ensuing loss of light were suggested An interesting example of such effects was afforded by a room with white walls and ceiling which, when empty, appeared to be brilliantly illuminated, but when the room was occupied by bulky, dark-coloured machinery the illumination was found to be inadequate At the conclusion of the meeting it was mentioned that a special course of lectures, each given by an expert on some special aspect of illumination, is being arranged to take place at the Polytechnic, Regent Street, starting in April next.

With its January issue *The Marine Observer* has entered upon its second year. The former Director of the Meteorological Office, Sir Napier Shaw, contributes an interesting communication, "A Meteorologist at Sea," a reflection on meteorology when traversing the Atlantic for the recent British Association meeting in Canada The reflection roughly compares official meteorology as undertaken by Admiral Fitz-Roy in 1855-1865 with official meteorology as controlled by Sir Napier from 1900 until 1924. At the commencement of Sir Napier's official career at the Meteorological Office, a quarter of a century ago, weather observations were obtainable only at the central weather offices of different countries, and the area embraced was very much limited Now the daily map obtained embraces practically the whole of the Northern Hemisphere. It is only a little more than 60 years ago that charting the weather on daily maps was introduced into Great Britain by Admiral Fitz-Roy Much information is given in the periodical bearing on ships' wireless weather news, by means of which every opportunity is afforded seamen of constructing their own weather charts when at sea.

In the January issue of *Science Progress* Mr F W. Shurlock, Principal of Derby Technical College, gives an account of the Rev A Bennet, F R.S, curate of Wirksworth, near Matlock, and inventor of the gold leaf electrometer Unfortunately, the "Dictionary of National Biography" gives no account of Bennet and ascribes the invention of the instrument to George John Singer. The "Encyclopædia Britannica" and Wiedemann's "Elektricität" both give the credit to Bennet, and cite his paper in the Transactions of the Royal Society for 1787, in which the instrument is described. It is dated "Wirksworth, Sept. 14, 1786," and as Singer was born in this year there can be no question of priority Mr. Shurlock quotes the description of the instrument, the method adopted for getting an electric charge from the air by means of a flame and the method of doubling the charge obtained Bennet's Royal Society papers form the basis of his book, "New Experiments on Electricity," published at Derby in 1789 He appears to have been a master at the Free Grammar School at Wirksworth, and there is a quaint portrait of him in the vestry of the parish church. He became rector of Fenny Bentley near Ashbourne in 1796 and died there in 1799.

The "Arcadia" projector, shown in operation at the King's Cross Cinema on February 4, has several novel and distinct features Hitherto the projection of "living pictures" has been based on the use of an automatic shutter alternately opening and closing, and presenting a rapid succession of "still" effects. The shutter causes a rapid alternation of light and darkness and is liable to cause more or less flicker. The new projector makes use of a complex arrangement of rotating mirrors, whereby successive pictures are imposed, but throughout the process there is substantially the same amount of light on the screen, and it is claimed that this removes one potential cause of eye-strain. In addition the method gives rise to a certain degree of stereoscopic effect The mechanism of the projector and the method of feeding the film also present novel features, conducive to greater steadiness and more silent running, and the amount of wear and tear of the film is stated to be very much reduced. A similar projector was demonstrated at the Imperial College, South Kensington, on February 10, 1921, and described in our issue of February 24, 1921, p. 841.

THE recently amalgamated firms of T. Cooke and Sons, Ltd., and Troughton and Simms, Ltd, 3 Broadway, Westminster, S.W 1, which went into voluntary liquidation several months ago, inform us that this state of affairs has now been satisfactorily terminated They wish it to be known that their facilities for designing and manufacturing high-grade scientific instruments and apparatus in large quantities have been retained intact, so that they are able to deal with orders as hitherto

MESSRS Adam Hilger, Ltd, have recently issued a handsome catalogue of their various manufactures It includes thirteen sections and is provided with a thumb index for ready reference as well as a general index at the end. The instruments described and illustrated in the sections come under the following headings:—Echelon diffraction gratings and Lummer-Gehrcke parallel plates (including echelon gratings having as many as 56 plates), spectrometers and goniometers, wave-length spectrometers, monochromators and specialised spectroscopes, spectrographs, accessories for spectrometers and spectrographs (including, among other things, heliostats, vacuum tubes, thermopiles and high purity electrodes of copper, iron, carbon and nickel), spectrophotometers, colorimeters, and apparatus for sensitometry (including the new Judd Lewis sector photometer), diffraction gratings; micrometers, etc, polarimeters and refractometers, Michelson, Fabry and Perot, and Hilger interferometers, spectroscopic apparatus for high resolving power, optical work, and the Low-Hilger audiometer. The instruments are well described and appear to be constructed with the care and with the view of convenience in use for which this firm is well known It is unfortunate that they cannot be produced at a lower price, however, as many to whom they would be of great value will find some of the charges prohibitive.

MESSRS. Gallenkamp and Co., Ltd, of 19 Sun Street, Finsbury Square, London, are to be congratulated on the new issue of their catalogue of apparatus for the examination of soil Until now, the recent striking advances in the technique of agricultural science, especially in physics and physical chemistry, have not induced the scientific apparatus firms and instrument makers to introduce the new apparatus to general notice This has been a real disadvantage to the research worker in soils It has usually been possible to persuade a firm to make a copy of some particular apparatus, the construction of which was beyond the ordinary laboratory facilities, but this is a very expensive way, as all the special costs are chargeable to the one apparatus. On the other hand, when an apparatus is listed in a catalogue, not only does it bear a smaller share of the overhead charges, but the publicity usually results in increased sales, which act in the same direction Messrs Gallenkamp's catalogue is divided into five sections soil sampling tools, physical properties of soil, soil solution, chemical analysis of soil, and soil meteorology Each of these sections contains items that well show the recent advances in the technique of agricultural science The newer forms of soil sampling tools are to be commended, and in the sections on physical properties of soil and soil solution, prominence is given to apparatus devised at the Rothamsted Experimental Station The section on soil meteorology has been carefully thought out and should be of considerable use in the development of work that, coming on the border line between meteorology and soil physics, has been rather neglected

MESSRS. Longmans and Co have in preparation a new and cheaper edition of Thorburn's "British Birds" The work will be in four volumes, illustrated by 192 coloured plates reproduced from new drawings by the author It is hoped to issue the first volume in March, the second in the autumn, and the remaining two volumes in 1926

SOME 1900 books on geology, palæontology, and mineralogy from the libraries of the late Sir Jethro J. H. Teall, and Messrs T W Reader and E A. Walford, are offered for sale in Catalogue No 123 by Messrs Dulau and Co, Ltd, 34 Margaret Street, W 1, together with a number of other works on fossil plants, anthropology, archæology, and zoology Copies of the catalogue can be obtained on application

Our Astronomical Column.

PHOTOGRAPHY OF THE ASTRONOMISCHE GESELLSCHAFT ZONES.—Prof Schlesinger gave an interesting account at the meeting of the Royal Astronomical Society on Jan. 10 of the reobservation by photography, at Allegheny Observatory, of some of these zones The novelty of the method lies in the size of the plates used, some of which are 5° in the side, others 12½°. The lens is a triple one, and the only form of distortion present is a tendency for bright stars to appear slightly displaced away from the centre as compared with faint ones; the amount near the edge is 0·06″ per magnitude. As each star is present on at least two plates, with the shift generally in opposite directions, no systematic magnitude error is introduced.

Although the scale is only half that of the Astrographic plates, the excellence of the lens is such that the probable error of each star image is only 0·18″.

Incidentally, the measures give the means of determining magnitude error in the Astr. Gesell. Catalogues For on plotting the differences of R A, Allegheny *minus* A G, for different magnitudes, the abscissa being Right Ascension, sine curves are obtained due to the solar motion The zero line of these curves is found to alter with the magnitude, now as magnitude equation on the photographs is shown to be eliminated in the mean, the effect must be due to the equation in the A G. Catalogues

Prof. Schlesinger is on his way to South Africa to inaugurate the photographic work with the instrument which is being sent there from Yale Observatory. He hopes to return in time for the meeting of the Astronomical Union at Cambridge in July. It may be mentioned that the 12½° × 12½° plates are a quarter of an inch thick and weigh 10 lb It would only need some 270 of these plates to cover the entire celestial sphere, so that the taking of the plates is a much less serious matter than that involved in the Astrographic Catalogue. The chief labour lies in the measurement and reduction.

Research Items.

THE PRESERVATIVE PROPERTIES OF HOPS.—For many years it has been assumed that the preservative properties of hops are directly proportional to the percentage soft resin content. In view, however, of the objections inherent in Brown's method of evaluating the former, it is welcome to find in a recent paper by Mr A Chaston Chapman (Jour Inst. Brew., 1925, xxxi 13) the description of an improved biological method To varying amounts of a 1 per cent. aqueous infusion of the hops, in a medium of nutrient agar, were added a few drops of a culture of an organism isolated from raw sugar, and specially sensitive to the inhibitory effects of hop extract. After incubation for 18 hours at 37° C on petri dishes, the mixtures were arranged in order of bacterial development, the end-point being represented by a dish containing few or no colonies, followed by one containing a large number The end-points were sharp and concordant, and within reasonable limits, were independent of the strength of the infusion and of the number of successive digestions of the same sample The author suggests that the preservative material, though highly insoluble, is being produced continuously during the extraction Whereas no quantitative connexion between the soft resin content and the preservative value is apparent, experiments on the cold and ordinary storage of hops show that both these properties diminish at a slower rate in the former case Apparently the two properties are associated in some way not yet clear, the quality rather than the quantity of preservative material being the important factor. Methods of estimating resin content by direct extraction are criticised, and an improvement giving higher results is suggested for soft resins. These are now extracted in a Soxhlet apparatus by petroleum ether from the total resin solution spread on an Adams milk-analysis paper.

DETERIORATION OF STRUCTURES IN THE SEA.—The fourth (interim) report of the Committee of the Institution of Civil Engineers on the Deterioration of Structures in Sea-water was published in December 1924, although the report itself is dated September 1923 and deals, for the most part, with investigations carried out in 1922 It includes a paper by Mr. E J M'Kaig and Dr. J Newton Friend describing a steel landing-stage at Weston-super-Mare which, after standing for fourteen years, developed structural defects and had to be taken down. One point of interest was the unexpectedly large amount of corrosion at the point where the piles entered the sea-bottom, due, apparently, to the slow drift of sand against the piles Other evidence also suggests that a very slight amount of mechanical wear greatly accelerated the chemical action of the sea-water on the steel Investigations relating to the preservation of timber from marine boring animals are reported on by Prof G Barger and Mr. C. M Yonge. As the work of the latter only extended over a period of six weeks, it was scarcely to be expected that much would be added to our knowledge of the life-history of Teredo The results of experiments in poisoning the larvæ with the arsenic compound "D M." are in striking contrast to the American observations recently reviewed in NATURE (November 22, 1924, p. 745). The species studied at Plymouth by Mr. Yonge was identified as *Teredo norvegica*; Prof. Barger does not give the name of the species which he observed at Lowestoft, but as he refers to "Teredo" as a "species," it is plain that he does not consider the point of much importance. An account is given by Mr. J. M'Glashan and the late Dr. N. Annandale, of damage done to brickwork in the Calcutta docks by the boring mollusc *Martesia fluminalis*. It should have been mentioned that Dr. Annandale's report printed here was published more than a year ago in the Journal of the Asiatic Society of Bengal (vol. xviii. No 10, p 555).

EXTINCT RHINOCEROSES OF CHINA.—The Geological Survey of China has published an important work by Dr. Ringström of Upsala on the Rhinoceros and Hipparion Fauna of North China (Provinces of Shansi, Shensi, and Honan). The present volume is part iv., series C of volume i., 1924, and deals entirely with the rhinoceroses In it a new genus of the short-legged teleocerine rhinoceroses is described under the name Chilotherium. A new genus of great interest, Sinotherium, of which Ringström had already published a preliminary account, is also here more fully described The genus is closely allied to Elasmotherium, that curious rhinoceros with extraordinary complicated teeth and large hump over the eyes and nose, of which the British Museum has recently acquired a fine skull The paper is fully illustrated with many text-figures and twelve plates, and its value is further enhanced in that the author gives his views on the position of certain Asiatic and European rhinoceroses.

AN AMERICAN EXTINCT FAUNA.—A bulletin of the American Museum of Natural History (vol 50, article 2) contains a third part of Dr. W D Matthew's studies on the Snake Creek fauna In it will be found a short notice of the stratigraphy of these important Miocene and Pliocene quarries whence the specimens came, together with remarks on the distinctions between the faunal zones and correlation of the faunas. The list of the vertebrate fauna, numbering more than a hundred species of mammals and including the celebrated tooth of *Hesperopithecus haroldcookii*, together with a sprinkling of birds, reptiles, and amphibia, is an impressive one. The bulk of the paper is devoted to an account of the various forms and, as is usual with this author, is no mere dry description, but is illuminated throughout by his discussion and views as to the evolution and relationship of the various forms, such as the phylogeny of the Canidæ and questions concerning the horses.

THE METEOR CRATER OF ARIZONA.—The Indians of Northern Arizona have a legend that a god visited them from heaven in a great chariot of fire which illuminated the sky and finally disappeared into the ground. It seems probable that the chariot was the gigantic meteorite which has been held responsible for the origin of the remarkable crater of Canyon Diablo. That the impact theory is correct seems to be established by the work of D. M. Barringer (Proc. Acad. Nat. Sci. Philadelphia, 1924, p. 275) He predicted in 1909 that the main bulk of the meteorite would be found under the southern wall of the crater. An exploratory boring has now been sunk near the southern rim, and at a depth of 1346 ft., highly oxidised meteoric iron was met with After passing through 30 ft. of this material the tools jammed, and no further progress was possible. Barringer considers the main meteorite approached the earth from the north at an angle of roughly 45°, leaving a scattered trail of the well-known Canyon Diablo meteorites. These have been found to contain platinum, and according to the *Winslow Mail*, of Arizona, a company has now been formed

to mine the deeply buried mass, which has been estimated to weigh a thousand million tons, by running drifts into it from the low country to the south of the crater rim The unique history of Meteor Crater should therefore be gradually disclosed during the next few years more completely than could ever have been anticipated before the possibility of platinum suggested mining exploitation.

PETROLEUM: ITS GENESIS AND GEOLOGY.—An article from the pen of Prof James Park and bearing this title appeared in the September number of the New Zealand Journal of Science and Technology (1924), it presents a very fair résumé of the subject, though it was obviously written for the purpose of general knowledge rather than to pave the way for possible oil explorations within the Dominion From the tectonic point of view New Zealand, as is the case with Australia, does not offer inducement as a country of potential petroleum reserves, though evidence of oil is by no means lacking, this does not, however, imply accumulation on a commercial scale. The author makes the interesting statement that "The seepages of oil found at Taranaki, and at Waiotapu in the King-country, New Zealand, occur in Tertiary rocks; and there is good reason for the belief that the oil has originated from the destructive distillation of the underlying seams of lignitic coal" This theory, even if well founded, tends to make it all the more improbable that there is any economic future for oilfield development in this country This is the only specific reference to petroleum in New Zealand In the paragraphs discussing the general geology of petroleum, the author refers to the porosity of oil-sands and states that "a porosity of 10 per cent is equal to 750 barrels of oil per acre-foot. The recoverable oil ranges from 50 to 75 per cent of the oil in the sands" This last sentence is open to some doubt, especially with present-day methods of oil production, in practice a 30 per cent recovery is considered good, Uren places the maximum at about 40 per cent, and with a 25 per cent porosity and complete saturation this could probably be achieved Writing of oil migration, the author attributes this to "the differences of the specific gravities of oil and water" as being "the most powerful cause"; the researches of Munn and others have demonstrated clearly that movement and pressure of underground water are far more potent causes, as, indeed, may be gas pressure and capillary attraction. The article is, on the whole, a curious mixture of orthodox statement and original comment; it is in many respects to be regretted that the author does not also give us a fuller description of the known occurrences of bitumen in his country, notwithstanding that they may have little commercial value.

SOME USES OF PEAT.—One commonly regards peat in domestic use as a form of clean, cheap, though not always very efficient fuel, and such it probably is in most countries. It may come as a surprise to some people, therefore, to learn that in that land of varied and abundant fuels, the United States, by far the greatest quantity of peat produced is utilised in the form of fertilisers or as an ingredient of fertilisers, no less than 57,907 tons being marketed for this purpose in 1923, at a gross value of 351,641 dollars. The bulk of the United States peat comes from Illinois, New Jersey and California contributing the second and third largest outputs respectively. The use of peat as a stock-food is the next important activity in the industry, more than 3000 tons being produced for this purpose in the same year. As a fuel, the production (hence consumption) was practically negligible; in fact no return was made at all for 1923, and only 1040 tons were thus absorbed in the previous year Other uses (according to Mr. K. W. Cottrell in Mineral Resources of the United States for 1923, part 2) include its employment as peat moss, stable litter and packing material, much of which is included under the annual return for stock-food A somewhat curious fact is that peat moss imported for consumption in the United States has shown a steady increase during five years from 1919, when 464 tons were introduced, to 1923, when nearly 600 tons at a value of 43,184 dollars were imported, presumably from northern Europe, where the Sphagnaceæ are important constituents of peat Peat rich in these mosses has in other countries been successfully used in the manufacture of blankets, rugs, cardboard and cork-like materials, and it may be that some such use is being found for it in the United States, though the present report makes no mention of the purpose for which peat moss is being imported

RESOURCES OF ARCTIC RUSSIA.—Under the Scientific-Technical Department of the Supreme Council of National Economy, Transactions of the Northern Scientific and Economic Expedition, Petrograd and Moscow, 1920–1924 (*in Russian*), are published the results of several expeditions for the exploration of natural resources of Arctic Russia The publication appears in separate parts, each one dealing with a special problem Most of the work has been directed towards the exploration of the mineral wealth of the country, and many important discoveries are recorded. Thus the report by I. I. Ginsburg (No 7 of the Transactions, pp 64) contains an exhaustive survey of the mineral resources of the coasts of the Kandalaksha Gulf of the White Sea, where gold has been found and extensive beds of mica have been studied, local silver and lead ores are also described, and sketch maps of mineral resources are given No. 18 of the Transactions (pp 75, 1924), by Beliankin and Kupletsky, and No. 20 (pp. 43, 1924), by Beliankin, Vlodavez, and Shimpf, contain further information on the mineral resources of the same territory collected during the expeditions of 1917 and 1922 respectively, these two papers include also considerable data on petrography and geology of the country No 16 of the Transactions, by A Fersman (86 pp, 1 map, 1923), includes a series of abridged reports of different authors on the results of expeditions to the Khibin ridge of the Kola peninsula, where a very extensive geographical, geological, and geochemical survey was organised during the years 1920, 1921, and 1922, full reports of the expeditions will be published in two volumes when all the materials collected are worked out Paper No 19 (pp 102, summary in English), by Prof K N Derjugin, presents results of exhaustive hydrological and biological exploration of the Barents Sea during the years 1921–1923 The author gives new evidence to prove that, besides the annual oscillations of temperature of water, there exist periodic variations in the Atlantic currents which appear to be subject to a cycle of 8-9 years Other hydrological elements, distribution of salinity and of oxygen, degree of transparency of water and character of ground, are also discussed. Lists of fauna are given (including descriptions of several new forms), and the conclusion is reached that the fauna of the Barents Sea is not arctic, but only sub-arctic, in its composition. The authors believe that periodical variations in the thermical state of the Barents Sea have a strong influence on the climate of Northern Europe.

WEATHER IN RHODESIA.—The Proceedings of the Rhodesia Scientific Association, vol. xxii., contains a discussion on "The Problem of Seasonal Forecasting," by Mr. C. L. Robertson. The method of

cycles is dealt with, but the longest local record available is only continuous for 35 years, which is quite insufficient Severe droughts are said to occur within a year or two of sunspot minima and heavy rains within a year or two of sunspot maxima A 19-year cycle, based on pressure variations, is suggested as influencing Rhodesian weather. Maps are given showing the variations of pressure over the globe for the months of February, May, August, and November Reference is made to the pressure values in the southern hemisphere to show the relation to Rhodesian weather Areas of high pressure, important centres of action for South African weather, are shown in the South Indian, South Atlantic, and South Pacific Oceans There is a movement of these centres to the north and south, and also to east and west The tracks are said to deviate from an average mean track, and the 19 years' periodicity is attributed to this movement Much detail is given with reference to the various cycles, and the inquirer will find much of interest. A connexion is referred to between the south-west monsoon rainfall in India and the rainfall along the east coast of Africa down to Rhodesia Based on the assumptions obtained, seasonal forecasts are being made and probably in time some success will be gained

HYDRODYNAMICS AND ELECTRICAL ANALOGIES —In the December issue of the *Journal de Physique*, Prof V Bjerknes shows how the general equations of hydrodynamics may be transformed so as to exhibit the close analogy between the movements and forces in the fluid and the currents and forces in electrodynamics By means of rotating cylinders, and arrangements for producing bodies the volumes of which pulsate about a mean value, or oscillate about mean positions, he has shown that the analogy is true experimentally He points out that both his theoretical and his experimental work are but generalisations and improvements of results published by his father forty-five years ago Amongst the analogous systems referred to by the author may be mentioned the lines of flow about a pulsating sphere and the lines of force about a magnetic pole, the lines of flow due to an oscillating sphere and the lines of force of a short magnet, the lines of flow due to two parallel cylinders rotating in opposite directions and the lines of force due to two parallel electric currents flowing in opposite directions, a cylinder rotating in a stream of fluid (the Magnus effect) and a wire carrying electric current in a magnetic field.

HEATS OF OXIDATION —The heats of oxidation of certain metals in a pure state have been redetermined by J. E Moose and S W Parr (J Amer Chem Soc, Dec 1924). A very accurate bomb method was used. The values, in calories per gram of metal, for some of the more important metals are aluminium, 6970, beryllium, 14,879, zinc, 1298, magnesium, 5996, cerium, 1661

ISOLATION OF HYDROXYLAMINE —C de W. Hurd and H J Blounstein, in the Journal of the American Chemical Society for January, describe a new method of isolating free hydroxylamine from the hydrochloride The latter is decomposed with a butyl alcohol solution of sodium butylate, the sodium chloride is filtered off and the filtrate cooled to −10°, when half the hydroxylamine crystallises out. Methods of utilising the half remaining in solution are described.

ATOMIC WEIGHTS OF SILVER AND CARBON —The atomic weights of silver and carbon have recently been determined by Dr. G. Dean by the reduction of pure silver cyanide and cyanate in a current of hydrogen (J Chem. Soc., Dec. 1924). Assuming O = 16, Ag = 107 88, and N = 14·008, then the ratio AgCN . Ag gave C = 12·002 ± 0·001. Similarly, the ratio AgCNO : Ag gave C = 12·003 ± 0·001. By combining these ratios, and assuming only that O = 16, then Ag = 107·871, and the radical CN = 26·008, which, on subtraction of 14·008, gives C = 12·000.

ELECTROLYSIS OF SOME ORGANIC SALTS —The electrolysis of salts of some alkyloxyacids is described by D A Fairweather in the Proceedings of the Royal Society of Edinburgh (1924, vol. 45, Part I., No 4). The potassium salts of ethyl ethoxymalonic, ethyl diethoxysuccinic, and ethoxyacetic acids, and sodium amyloxyacetate were used. The chief products are of an aldehydic nature. Hofer and Moest's explanation of the formation of formaldehyde from the electrolysis of sodium glycollate is shown to be applicable to the cases studied, in one case (potassium ethyl ethoxymalonate) the intermediate compound postulated by these investigators was identified in the electrolysis products, owing to its being quite stable.

CARBONISATION TESTS —The Fuel Research Board has issued a Technical Paper No 10 on the carbonisation of a South Wales gas coal (Meiros Colliery, Llanharan) in Glover-West continuous vertical retorts. The report gives the results of carbonisation tests resembling in scope and procedure those made on several gas coals from other coalfields (See F.R B. Report, 1920–21, and Technical Paper No 8) In particular, the effect of steaming was observed and the variation in the results obtained when the percentage of steam was increased from nil to 20 per cent of the coal treated The results are fully tabulated and summarised in conjunction with those obtained from other gas coals, which they follow in general lines The tests form a part of the scheme of the Board to prosecute a survey of the national coal resources, and the compilation and ascertainment of such results will undoubtedly have a value which will be greater as the data available become more complete

EXPANSION OF ALLOYS.—The eighty-fifth report from the Research Institute for Iron, Steel, and other Metals, Sendai, by Kotaro Honda and Yosikadu Okubo, deals with the measurement of the coefficients of thermal expansion for certain alloys. The apparatus used was the same as that constructed some years ago by Honda. It is a modified form of Chevenard's dilatometer The entire apparatus can, if necessary, be enclosed in a bell jar which can be evacuated so that the oxidation of metal specimens is avoided. Data are given for certain aluminium alloys, particularly those used in aviation The results obtained with alloys of iron and nickel are interesting On adding nickel to iron, the coefficient of expansion decreases slightly up to 18 per cent. of nickel and then increases to 25 per cent. From 25 per cent it decreases rapidly to 36 per cent. and afterwards increases, rapidly at first, and above 50 per cent. gradually, up to pure nickel These results coincide with those of Guillaume, the alloy of minimum coefficient of expansion being approximately of the same composition as that of invar So far as iron-cobalt alloys are concerned, the variations are much smaller. On adding cobalt to iron the coefficient of expansion decreases gradually to a minimum of 48 per cent., and rises gradually to the concentration of pure cobalt.

The Water Supply of Egypt and the Sudan.

IN the report recently issued[1] by the Physical Department of Egypt on the discharges and levels of the Nile and the rains of the Nile Basin for 1919, we have a revival of the reports on the rains of the Nile Basin which, after appearing for eight years, were discontinued on the outbreak of the War.

This report differs from its predecessors in an important respect; the volumes discharged by the Nile and its tributaries now take the first place, and the rainfall measurements form but a minor portion of the volume. This is an indication of the advance which has been made in late years by the Physical Department in the accurate gauging of the Nile supply, a matter of the highest importance both to Egypt and to the Sudan. While formerly most of the determinations were dependent on the accuracy of curves constructed to show the relation between a gauge reading and the corresponding volume of the discharge, we are now presented with no less than 465 measured discharges taken during the year 1919. Of these 210 were on the Blue Nile, 74 on the White Nile, and 138 on the main stream. This gives a precision to the results and an authority to the deductions which may be drawn from them that puts the hydrographic work on the Nile on a very high level.

The discharges have been measured with Gurley's pattern of current meter, and these instruments are rated from time to time at Cairo. It has been suggested that discharges measured during the flood are too large in consequence of the meter being affected by the turbulency of the water, but recent experiments by Mr. B. H. Wade show that this effect has been much overestimated.

The characteristics of the Nile regimen are well brought out in the table; the low stage flow of only 50 cubic metres per second of the Blue Nile in April, and the rapid rise to 8000 cubic metres per second at the beginning of September, in a year when the Abyssinian rainfall was about 30 per cent. below the average, shows how vast a volume of water pours down to the Sudan and Egypt at this season of the year. There is at this time ample water for the needs of the Sudan in the neighbourhood of the Blue Nile when Egypt is receiving more than its land can possibly utilise.

The discharges of the White Nile show a wholly different type of supply, it varied from about 600 cubic metres per second in April and May to 1300 cubic metres per second in October and November, an increase due to water brought in by the Sobat river, which in 1919 received an unusually small supply from the southern plateau of Abyssinia.

There are now 48 river gauges on the Nile and its tributaries south of Wadi Halfa which are read regularly, besides 9 on Lakes Victoria, Kioga, and Albert in Uganda.

The rainfall throughout the Nile Basin is presented in a series of tables, and in most places it was below the normal in 1919. Consequently the level of the lakes on the Lake Plateau of Uganda fell generally, on the Bahrel Jebel the summer rainfall was good, but the extent of marsh in this region prevents the discharge in the lower reaches from gaining by it. The rainfall on the Abyssinian plateau was considerably below the normal, so that the volume passing Wadi Halfa was below the average throughout the year except in July, August, and September, and in November the defect reached 23 per cent.

When we remember that the Nile for the last two thousand miles of its course flows through arid or semi-arid regions, the importance of accurate hydrographical information such as this cannot be overestimated.

Occurrence and Use of Bitumen.

IN a recent report (No. 625) of the Mines Branch of the Canadian Department of Mines, Mr. Sydney C. Ells contributes a summary account of the nature, mode of occurrence, exploitation, and commercial development of the famous "tar sands" of Northern Alberta, Canada. The report forms an appendix to the author's former "Preliminary Report on the Bituminous Sands of Northern Alberta," No. 281, published in 1914, but for some years out of print. The present summary contains the results of further field-survey of the deposits, including examination and sampling of the sands, a résumé of modern methods of recovery of the bitumen from the sand, and some data concerning the laying of demonstration pavements and roadways.

The principal area of exposure of these sands is along the Athabasca River, outcrops occurring for a distance of more than 220 miles. The deposits are probably of Cretaceous age, though the origin of the bitumen is uncertain, a question which, however, is to form the subject of a report already in preparation. The impregnation varies with the texture of the sand, as would be expected, medium and moderately compact deposits being the richest, finely-graded material being the poorest in bitumen content. Attention is directed to the existence of impervious partings or strata within the deposits which act as horizons of concentration of the bitumen from overlying sands, presumably by downward migration. The more fluid seepages, known as "tar springs," are shown to have originated by lateral migration from slightly inclined beds of particularly rich, coarse-grained sand, the author states that such springs are not of commercial value as sources of bitumen, and further, that it is erroneous to regard them as indications of oil-pools, as has been done by certain geologists who have studied this region. The average bitumen content ranges from 20 per cent. to 25 per cent. in the richest deposits, to 15 per cent. in the normal impregnated sands; the crude bituminous sand has a gravity of 1·75 and a moisture factor of 1·3 per cent.

The commercial application of this material to paving and road construction must be considered as still being in the experimental stage, though results based on eight years of observation on a highway surfaced in three different ways, namely, with sheet asphalt, bitulithic and bituminous concrete, are certainly encouraging, since at the time of writing the author states that "the pavement [*i.e.* road surface] was still in first-class condition, and had required no repairs," notwithstanding that heavy traffic included, apart from motor cars, vehicles carrying loads up to ten tons. Crude bituminous sand is not recommended *per se* as paving material owing to its unbalanced mineral aggregate, lack of uniformity and to freight charges, though it is considered that an attempt should be made to produce an artificial mixture in which the inherent properties and qualities of the sand can be utilised to the greatest advantage. The report concludes with a valuable summary of processes employed for refining bituminous deposits of this character.

University and Educational Intelligence.

LEEDS.—Applications are invited for a lectureship in bacteriology, particulars of which may be obtained from the registrar. The latest date for the receipt of applications is February 23.

LONDON.—On Monday, February 23, Prof. W. T. Gordon will begin a course of twelve Swiney lectures on "The Geological History of Plants," at King's College, at 5.30 o'clock. The succeeding lectures will be given on February 25, March 2, 4, 9, 11, 16, 18, 23, 25, 30, and April 1. Admission will be free.

A free public lecture (in English) on "The Relation of Paralysis Agitans to the Parkinsonian Syndrome of Epidemic Encephalitis" will be given in the Lecture Hall of the Royal Society of Medicine, 1 Wimpole Street, W.1, by Prof. R. Cruchet, of the University of Bordeaux, at 5 o'clock on Wednesday, February 25.

A course of four public lectures on "Puerperal Sepsis" will be given by Prof. B. P. Watson, at St. Thomas's Hospital Medical School on March 2, 3, 4, and 5, at 5 o'clock.

PROF. WIELAND of Königsberg has been offered the chair of pharmacology at the University of Frankfurt.

DR. FRITZ HILDEBRANDT, lecturer at the University of Heidelberg, has been offered the chair of pharmacology at the Medical Academy in Dusseldorf.

DR. PERCY BRIGL, first assistant at the Institute of physiological chemistry in the University of Tübingen, has been nominated professor and director of the Institute of Agricultural Chemistry at the Agricultural Hochschule at Hohenheim.

DR. FRIEDRICH PASCHEN, who was recently appointed president of the Physikalisch-Technische Reichsanstalt, has been elected to an honorary professorship in the philosophical faculty of the University of Berlin.

NOTICE is given that the examinations for the award of the Tate Scholarships in engineering, science, and domestic science at Battersea Polytechnic for the session 1925–1926 will be held on June 9 and succeeding days. The annual value of the scholarships is from 20*l.* to 30*l.* each, with free tuition, and the tenure is three years. The last date of entry is April 18.

A LECTURER in botany at University College, Colombo, will shortly be appointed. Candidates for the post must hold a first-class honours British degree, with botany as the principal subject, or have equivalent qualifications, and should have had experience of lecturing or teaching. Particulars of the appointment and copies of the necessary forms of application are obtainable from the Private Secretary (Appointments), Colonial Office, Downing Street, S.W.1. The completed forms must be returned by at latest March 1.

A JUDICIAL decision of interest to all who are concerned with educational finance was announced in the November number of *School Life*, the official journal of the Washington Bureau of Education. The Supreme Court of Oklahoma upheld the validity of a State appropriation to aid in paying teachers' salaries in districts that had levied the maximum school tax and still could not maintain their schools. The court held that the burden of education rests on the State, and that the local rates are in the nature of aid to the State, which is bound to take such measures as are necessary for financing the school system, so as to afford equality of opportunity throughout the State.

Early Science at Oxford.

February 15, 1683–4. Mr. Aston sent an account of ye ascent of water in a bolt-head, a great while *before* freezing; and that a peice of Ice, of 3½ inches thick, 4 broad, and a foot long, bore, in ye middle, ye weight of 350 lb, but with 400 lb, after some time, it broke, and (which is most surprising) that ye ice on ye Thames of late was not above 11 inches thick. The same letter told us, that Ice was asserted to be to water in weight, as 7 to 8: which differs not much from Mr. Desmasters late experiment.

Then my Lord Bishop of Ferns his Discourse, concerning Acousticks, and ye severall ways of improving the sense of hearing, was read.

Mr. Ballard acquainted ye company with his success in some late Experiments performed by order of ye company. A part of ye Rosemary stone (lately shewn us by Dr. Plot) after calcination in a charcoale fire, apply'd to a magnet as well as that which had been calcined in a seacoale fire. He chose to calcine it in a charcoale fire, haveing some suspicion it might receive some particles of iron, from ye seacoale, for he has formerly observed seacoal to be a kind of imperfect, or unripe iron-ore, because by an excessive heat of a forge it will flow, like molten metals, and then run to ye bottom of ye fire, where, haveing now lost all its combustible parts, it presently grows dead, and looking black, is cast out, a perfectly burnt cinder.

1686–7.—A letter from Dr. Garden of Aberdeen, Dec. 8, to Dr. Plot, gives an account of ye generation of ye small caterpillar, which infests blossoms of peares and apples, and destroys ye fruit *viz.* that they are not bred of mists and dews as Godartius thinks, but of eggs, from whence he draws several other inferences.

February 16, 1685–6.—Mr. Ash, secretary of the Philosophical Society of Dublin, described the case of a woman in ye North of Ireland, who fasted for ye space of eighteen weekes, and did not speak in almost all that time.—This gave Dr. Plot occasion to mention a silent woman now living at Wanborow in Wilts, who has not spoke in near twenty yeares, of whom he promises to procure a more full relation.

February 17, 1684–5.—A Nyctalops, or case of night-blindness, was described by Dr. Briggs. Being a schoolmaster, and able to answer such queries as shall be proposed to him, the Society agreed to send a list of queries, among which were: Whether this Person can see by Candle-light, in a darke room, any time of the Day? Whether, at any time, by candle-light darted through a Ball of water? Whether by ye light of Glow-wormes, rotten wood, Herrings heads &c.? Whether at any time, and by any light, with ye Bishop of Ferns his Spectacles? Whether his Eyes are equally affected?

A description of the Cicindela volans, by Mr. Waller, F.R.S. was read, and Dr. Plot affirm'd, that this Insect has been observed in Staffordshire.

Mr. Walker brought in an account of the prices of ye best wheat and mault at Oxford on the market-dayes next before Lady-day and Michaelmas for twenty yeares last past: by which it appeares, that the price of wheat for twenty yeares last past at a mean rate (*i.e.* one year with another) has been 5*s.* 4½*d.* ye bushell: mault, during the same time, in ye same market, at a mean rate, has sold at 2*s.* 11½*d.* ye bushell.

Mr. Cole promised patterns of Dyes of seven distinct colours from his Shell-fish, viz.: white, a fine yellowish green, a fair deep sea-green, a deep Watchet blew, a sullen purple, a deep dark sanguine, and ye bright Tyrian purple.
